1.0 EXECUTIVE SUMMARY/PROJECT ABSTRACT

The Goldsboro Housing Authority Mitigation Site (Site) is located in the northeast quadrant of the intersection of NC-581 and US-13 within the West Haven Apartments complex owned by the Goldsboro Housing Authority (GHA) in central Wayne County. As constructed the Site provides 799 stream mitigation units. The Site is located in United States Geological Survey (USGS) Hydrologic Unit 03020201200020 (North Carolina Division of Water Quality Subbasin 03-04-05) of the Neuse River Basin. The Site was identified to assist the North Carolina Ecosystem Enhancement Program in meeting mitigation goals. Primary activities at the Site included stream enhancement (levels I and II), creation of a Best Management Practice (BMP) constructed wetland, and replanting riparian areas with native vegetation. Project restoration efforts provided 799 Stream Mitigation Units and 1 Stormwater Wetland credit. This report summarizes data for year 2 (2010) monitoring.

The primary components of the restoration project included the following.

- 1. In keeping with the Neuse River Basinwide Management Plan developed by the North Carolina Division of Water Quality, a major goal of the project is to reduce sediment and other water quality stressors, nitrogen in particular, to the receiving watershed. This was achieved via the following measures:
 - a. Restore channel dimension throughout the Site to include bank resloping, benching and provision of reference appropriate width-depth ratios to reduce near bank stress and attendant erosion, and to move bedload towards equilibrium, thereby preventing future bank instability related to potential bed aggradation and/or degradation.
 - b. Replace the existing highly managed grass with an appropriate vegetated buffer providing root mass that will stabilize project banks, treating both overland and groundwater inputs.
 - c. Install a large stormwater wetland adjacent to Unnamed Tributary to Borden Field Ditch (UTBFD) designed to receive and provide off-line treatment to a portion of storm flows that meet or exceed the 1 inch storm, which will provide a significant sediment and biogeochemical sink for the inputs from the UTBFD watershed. The drainage area of the UTBFD is approximately 125 acres with approximately 50 acres of impervious surface. The existing Nitrogen load to the UTBFD at the location of the stormwater wetland is approximately 1229 pounds per year. It is anticipated that the stormwater wetland will receive flow during several storm events each year, as the typical 1 inch storm event and the one year design storm are expected to overtop the weir by 1.8 or 2.7 feet, respectively.
- 2. Attenuate storm flows and excess hydrologic energies associated with this highly urban watershed via 1 a,b,c.
- 3. Enhance the natural aesthetic of the project corridor
- 4. Increase local awareness of natural resources in an urban setting and the conditions necessary for their improvement/enhancement.

Based on interagency guidelines (USACE 2003), success criteria dictate that survival of woody species planted at mitigation sites should be at a minimum density of 320 stems per acre at the end of the third monitoring year. Subsequently, 290 stems per acre must be surviving at the end of year 4 and 260 stems per acre at the end of year 5. Based on the number of stems counted, average densities were measured at 580 planted stems per acre surviving in year 2 (2010). The dominant species identified at the Site were planted stems of river birch (*Betula nigra*) and sycamore (*Platanus occidentalis*). Supplemental planting of the Site is scheduled to occur in the winter of 2010.

Success criteria for Site streams with an assurance that project goals are being achieved will primarily be based on indicators and trends describing the stability of the channel and success of the riparian buffer. In addition, a minimum of two bankfull events must be documented within the standard 5 year monitoring period. In order for the monitoring to be considered complete, the bankfull events must occur in separate monitoring years. Year 2 (2010) monitoring measurements indicate that there have been minimal changes in the cross-sections as compared to as-built data. In addition, one bankfull event was documented in the field to occur February 5, 2010 with a second bankfull event occurring on September 26-27, 2010 after 4 inches of rain.

In summary, the Site achieved success criteria for vegetation and stream attributes in the Second Monitoring Year (2010). Summary information and data related to the occurrence of items such as beaver or encroachment and statistics related to performance of various project and monitoring elements can be found in table and figures within this report's appendices. Narrative background and supporting information formerly found in these reports can be found in the mitigation and restoration plan documents available on EEPs website. All raw data supporting the tables and figures in the appendices is available from EEP upon request.

2.0 METHODOLOGY

2.1 Vegetation Assessment

Following Site construction, three plots (20-meters by 5-meters) were established and monumented with metal rebar at all plot corners. Plots were surveyed in June 2010 for the year 2 (2010) monitoring season. Sampling was conducted as outlined in the *CVS-EEP Protocol for Recording Vegetation, Version 4.0* (Lee et al. 2006) (<u>http://cvs.bio.unc.edu/methods.htm</u>); results are included in Appendix C. The taxonomic standard for vegetation used for this document was *Flora of the Carolinas, Virginia, Georgia, and Surrounding Areas* (Weakley 2007). The locations of vegetation monitoring plots are depicted on Figure 2 in Appendix A.

2.2 Stream Assessment

Four permanent cross-sections were established after construction was completed. Measurements of each cross-section include points at all breaks in slope including top of bank, bankfull, and thalweg. Riffle cross-sections are classified using the Applied Fluvial Morphology (Rosgen 1996) stream classification system. Cross-section plots and data are included in Appendix D; the locations of cross-sections are depicted on Figure 2 in Appendix A.

DESCRIPTION OF WORKSHEE	TS IN THIS DOCUMENT
Metadata	Description of database file, the report worksheets, and a summary of project(s) and project data.
Proj, planted	Each project is listed with its PLANTED stems per acre, for each year. This excludes live stakes.
	Each project is listed with its TOTAL stems per acre, for each year. This includes live stakes, all planted stems,
Proj, total stems	and all natural/volunteer stems.
Plots	List of plots surveyed with location and summary data (live stems, dead stems, missing, etc.).
Vigor	Frequency distribution of vigor classes for stems for all plots.
Vigor by Spp	Frequency distribution of vigor classes listed by species.
Damage	List of most frequent damage classes with number of occurrences and percent of total stems impacted by each.
Damage by Spp	Damage values tallied by type for each species.
Damage by Plot	Damage values tallied by type for each plot.
	A matrix of the count of PLANTED living stems of each species for each plot; dead and missing stems are
ALL Stems by Plot and spp	excluded.
