1.0 EXECUTIVE SUMMARY

The North Carolina Ecosystem Enhancement Program (NCEEP) has completed restoration of 5178 linear feet of stream at the McIntyre Creek Restoration Site (hereafter referred to as the "Site") to assist in fulfilling stream and wetland mitigation goals in the area. The Site is located in Hornets Nest Park on the northern side of the City of Charlotte in Mecklenburg County. The Site is located in United States Geological Survey (USGS) Hydrologic Unit 03050101170020 (North Carolina Division of Water Quality [NCDWQ] Subbasin 03-08-34) of the Catawba River Basin and will service USGS 8-digit Cataloging Unit (CU) 03050101.

The Site is located within a NCEEP Targeted Local Watershed within the Long Creek watershed targeted for restoration. Waters in the Site drain approximately 2.5 miles into Long Creek (NCDWQ No. 11-120-[2.5]), which is listed as impaired for elevated levels of copper and turbidity negatively affecting aquatic life (NCDWQ 2010).

Prior to construction, the Site contained a degraded stream channel with a disturbed riparian buffer located within Hornets Nest Park. Site streams were characterized by eroding banks, channel widening, high sediment inputs from construction occurring in the upstream watershed and onsite bank erosion, and channel incision as indicated by bank-height-ratios ranging from 1.4 to 1.9. Surrounding land uses include commercial and residential areas with narrow riparian corridors adjacent to streams. Greater than 50-55 percent of the contributing watershed had been cleared and developed.

The goals and objectives of this project focus on improving local water quality, habitat, and stream stability. These goals were accomplished by the following.

- 1. Restoring stable channel morphology capable of moving flows and sediments provided by the watershed.
- 2. Improving water quality by reducing soil and riparian vegetation loss resulting from lateral erosion and bed degradation.
- 3. Improving aquatic habitat with bed variability and the use of in-stream structures.
- 4. Stabilizing tributaries draining into McIntyre Creek.
- 5. Providing educational opportunities through Mecklenburg County.
- 6. Improving the natural aesthetics of Hornets Nest Park.
- 7. Enhancing vegetation to provide habitat/food sources, shade the stream, filter overland runoff, and remove soil particles and other nutrients from stormwater.
- 8. Protecting a Site identified in a watershed that is listed as impaired for elevated levels of copper and turbidity (NCDWQ 2010).

Project construction was completed between March 2007-May 2008 and remediation construction to repair structures, stabilize banks, provide grade control, and dissipate stormwater energy was completed between August 2009-January 2010. The project restored 5178 linear feet of stream using Priority I restoration by constructing a new meandering channel within the McIntyre Creek floodplain, incorporating in-stream structures, installing grade control structures at the confluence with two tributaries, and planting with native forest species. Site activities provide 5178 Stream Mitigation Units. The Site will be protected by a permanent conservation easement held by the State of North Carolina.

Success criteria for stream restoration will be assessed using measurements of stream dimension, pattern, and profile; site photographs; visual assessments; and vegetation sampling. Cross-section measurements should show little or no change from the as-built cross-sections. If changes occur, evaluations will be

completed to determine whether changes are minor adjustments trending towards a more stable channel or if changes indicate movement towards an unstable condition. Annual measurement should indicate stable bedform features with little change from the as-built survey. Pools are expected to maintain depth with lower water surface slope and riffles are expected to remain shallower with steeper water surface slopes. Substrate measurements should indicate maintenance of distributions from the design phase and baseline measurements. In addition, there should be an absence of any significant aggradation or degradation of the stream channel.

Several areas of bank erosion are located throughout the project as the result of high stream flows, vertical banks, urbanized watershed, flashy flows, and tight radius of curvatures. These areas are depicted on Figures 2 and 2A-2B (Appendix B) and should continue to be monitored closely. Currently, the stream channel is considered to be within an acceptable range of variation compared to the as-built construction channel. However, due to the extensive impervious surfaces located within the upstream watershed the Site has periods of flashy flood flows even during smaller rain events. Flashy flood flows, compiled with minor bank instability has resulted in some degradation of the channel including eroding outer bends and slumping banks with loss of planted vegetation and reduced integrity of several structures. The loss of planted stems due to sloughing banks will most likely make the banks, particularly outer bends, more vulnerable to erosive flows and continued bank loss. Degradation is anticipated to continue to occur due to the characteristics of the watershed.

Success criteria for stream restoration will include documentation of two bankfull channel events during the monitoring period. In the event that less than two bankfull events occur during the first five years, monitoring will continue until the second event is documented. In addition, bankfull events must occur during separate monitoring years. Three bankfull events were documented during the year 1 (2010) monitoring season.

Vegetation success criteria dictate that an average density of 320 stems per acre must be surviving in the first three monitoring years. Subsequently, 290 stems per acre must be surviving in year 4 and 260 stems per acre in year 5. Stem counts will be based on an average of the evaluated vegetation plots. Based on the number of stems counted, average densities were measured at 429 stems per acre surviving in year 1 (2010). The dominant species identified at the Site were planted stems of river birch (*Betula nigra*), green ash (*Fraxinus pennsylvanica*), cherrybark oak (*Quercus pagoda*), and willow oak (*Quercus phellos*). Five of the ten individual plots met success criteria based on planted stems alone. Plots 2, 4, 7, 8, and 9 were below success criteria based on planted stems alone; however, when including naturally recruited stems of appropriate species such as box elder (*Acer negundo*), river birch (*Betula nigra*), green ash (*Fraxinus pennsylvanica*), and gum (*Nyssa* sp.) these plots were well-above 320 stems per acre.

Vegetation problem areas within the Site include a small patch of multiflora rose (*Rosa multiflora*) north of the stream near cross-section 3 and a patch of kudzu (*Pueraria lobata*) north of the stream near cross-section 2 (depicted on Figure 2, Appendix B). The kudzu is located on a filled area spreading from outside of the easement towards the stream channel.

Summary information and data related to the occurrence of items such as beaver or encroachment and statistics related to performance of various project and monitoring elements can be found in tables and figures within this report's appendices. Narrative background and supporting information formerly found in these reports can be found in the mitigation and restoration plan documents available on EEPs website. All raw data supporting the tables and figures in the appendices is available from EEP upon request.

2.0 METHODOLOGY

2.1 Vegetation Assessment

Ten vegetation plots were established and marked after construction with four foot metal U-bar post demarking the corners with a ten foot, three-quarter inch PVC at the origin. The plots are 10 meters square and are located randomly within the Site. These plots were surveyed in September for the year 1 (2010) monitoring season using the CVS-EEP Protocol for Recording Vegetation, Version 4.0 (Lee et al. 2006) (http://cvs.bio.unc.edu/methods.htm); results are included in Appendix C. The taxonomic standard for vegetation used for this document was Flora of the Carolinas, Virginia, Georgia, and Surrounding Areas (Weakley 2007).

2.2 Stream Assessment

Annual stream monitoring will be conducted following procedures established in the USDA Forest Service Manual, *Stream Channel Reference Sites* (Harrelson et. al 1994) and methodologies utilized in the Rosgen stream assessment and classification system (Rosgen 1994 and 1996). Four permanent cross-sections, two riffle and two pool, were established and will be used to evaluate stream dimension; locations are depicted on Figure 2 (Appendix B). Cross-sections are permanently monumented with 4-foot metal garden posts at each end point. Cross-sections will be surveyed to provide a detailed measurement of the stream and banks including points on the adjacent floodplain, top of bank, bankfull, breaks in slope, edge of water, and thalweg. Data will be used to calculate width-depth ratios, entrenchment ratios, and bank height ratios for each cross-section. In addition, photographs will be taken and pebble counts will be conducted at each permanent cross-section location annually.

Three approximately 1000-linear foot monitoring reaches were established and will be used to evaluated stream pattern and longitudinal profile; locations are depicted on Figure 2 (Appendix B). Measurement of channel pattern will include belt-width, meander length, and radius of curvature (only in year one). Subsequently, data will be used to calculated meander-width ratios. Longitudinal profile measurements will include average water surface slopes and facet slopes and pool-to-pool spacing. Ten permanent photo points were established throughout the restoration reach; locations are depicted on Figure 2 (Appendix B) and are included in Appendix B. In addition, visual stream morphology stability assessments will be completed in each of the three monitoring reaches annually to assess the channel bed, banks, and in-stream structures.

APPENDIX C VEGETATION PLOT DATA

- Table 7. Vegetation Plot Criteria Attainment
- Table 8. CVS Vegetation Plot Metadata
- Table 9. Total and Planted Stems by Plot and Species

Table 7. Vegetation Plot Criteria Attainment McIntyre Creek Restoration Site (EEP Project Number 234)

| Vegetation Plot ID | Vegetation Survival Threshold Met? | Tract Mean |
|--------------------|------------------------------------|------------|
| 1 | Yes | |
| 2 | No* | |
| 3 | Yes | |
| 4 | No* | |
| 5 | Yes | 700/ |
| 6 | Yes | 50% |
| 7 | No* | |
| 8 | No* | |
| 9 | No* | |
| 10 | Yes | |

^{*}Based on planted stems alone, these plots don't meet success criteria; however, when including naturally recruited stems of appropriate species such as box elder (Acer negundo), river birch (Betula nigra), green ash (Fraxinus pennsylvanica), and gum (Nyssa sp.) these plots were well-above 320 stems per acre.

Table 8. CVS Vegetation Plot Metadata McIntyre Creek Restoration Site (EEP Project Number 234)

| Report Prepared By | Corri Faquin |
|-----------------------------|---|
| Date Prepared | 9/28/2010 10:10 |
| database name | Axiom-EEP-2010-A.mdb |
| database location | C:\Axiom\Business\CVS Database\2010 |
| computer name | CORRI |
| file size | 40185856 |
| DESCRIPTION OF WORKSHEE | TS IN THIS DOCUMENT |
| Metadata | Description of database file, the report worksheets, and a summary of project(s) and project data. |
| Proj, planted | Each project is listed with its PLANTED stems per acre, for each year. This excludes live stakes. |
| Proj, total stems | Each project is listed with its TOTAL stems per acre, for each year. This includes live stakes, all planted stems, and all natural/volunteer stems. |
| Plots | List of plots surveyed with location and summary data (live stems, dead stems, missing, etc.). |
| Vigor | Frequency distribution of vigor classes for stems for all plots. |
| Vigor by Spp | Frequency distribution of vigor classes listed by species. |
| Damage | List of most frequent damage classes with number of occurrences and percent of total stems impacted by each. |
| Damage by Spp | Damage values tallied by type for each species. |
| Damage by Plot | Damage values tallied by type for each plot. |
| | A matrix of the count of PLANTED living stems of each species for each plot; dead and missing stems are |
| ALL Stems by Plot and spp | excluded. |
| PROJECT SUMMARY | |

APPENDIX E HYDROLOGY DATA

Table 12. Verification of Bankfull Events

Figure 3. Annual Climatic Data vs. 30-year Historic Data

Table 12. Verification of Bankfull Events

McInytre Creek Restoration Site (EEP Project Number 243)

| Date of Data Collection | Date of Occurrence | Method | Photo (if available) |
|----------------------------|--------------------|--|----------------------|
| September 23, 2010 | July 12, 2010 | Total of 2.14 inches* of rain reported to fall over 2 days (July 11-12, 2010), in addition to large wrack/debris piles and evidence of overbank flows within the adjacent floodplain. | 1-2 |
| September 23, 2010 | August 19, 2010 | Total of 1.1 inches* of rain reported to fall over 2 days (August 18-19, 2010) after a total of 4.43 inches* of rain the preceding 4 weeks, in addition to laid back vegetation and evidence of recent standing water within the floodplain. | 3 |
| October 18, 2010 | September 29, 2010 | Total of 4.04 inches* of rain reported to fall over 6 days (September 25-30, 2010). | |

^{*} Reported at KCLT Weather Station at the Charlotte Airport (Weatherunderground 2010).
