GEOLOGY AND MINERAL RESOURCES SECTION

This section shall, by law ". . .make such examination, survey, and mapping of the geology, mineralogy, and topography of the state, including their industrial and economic utilization, as it may consider necessary.

In carrying out its duties under this law, the section promotes the wise conservation and use of mineral resources by industry, commerce, agriculture, and other governmental agencies for the general welfare of the citizens of North Carolina.

The Section conducts a number of basic and applied research projects in environmental resource planning, mineral resource exploration, mineral statistics, and systematic geologic mapping. Services constitute a major portion of the Section's activities and include identifying rock and mineral samples submitted by the citizens of the state and providing consulting services and specially prepared reports to other agencies that require geological information.

The Geology and Mineral Resources Section publishes results of its research in its own series of Bulletins, Economic Papers, Information Circulars, Educational Series, Geologic Maps, and Special Publications. For a complete list of publications or more information about the Section please write: Geology and Mineral Resources Section, P. O. Box 27687, Raleigh, North Carolina 27611.

Acknowledgments

Dr. Gerald R. MacCarthy, late Professor of Geology at the University of North Carolina at Chapel Hill, did much of the initial work on this project prior to his retirement in 1965. This publication serves as a tribute to his efforts.

The authors wish to express their thanks to the Department of Geology for funding this project. Drs. David E. Dunn and Roy L. Ingram provided valuable assistance and encouragement during various stages of our work. Thanks are extended to Drs. Dunn and John J. W. Rogers who reviewed the manuscript.

The computer program that produced the catalogue listing was run on the IBM 360/75 computer at the University of North Carolina Computation Center.

Abstract

Seismograph station CHC operated on the campus of the University of North Carolina at Chapel Hill until December 31, 1970, when station operations ceased due to equipment problems and an increase in cultural noise in the surrounding area. This catalogue lists seismic events recorded during a fifteen year period when the station was fully functional.

As an introduction to those whose main interests lie outside the field of earthquake seismology, definitions are given for basic terms such as earthquake, epicenter, magnitude, and intensity. Descriptions are provided for the three major types of seismic waves: compressional, dilational, and surface. Because of confusion that often develops when the "bigness" of earthquakes is discussed, the Richter scale is described and a table showing the relationship between intensity, magnitude, and released energy is given.

In the fifteen years of operation, seismograph station CHC recorded 3,040 recognized events. Between 1955 and 1965, Dr. Gerald R. MacCarthy, then Professor of Geology, listed all detected disturbances on index cards. The authors of this catalogue checked these cards against the original seismograms, updated all information to December 31, 1970, and typed a computer card for each seismic event. The data listed on these cards include: date, origin time (Greenwich Mean Time) of the earthquake, latitude and longitude of the epicenter, arrival time of the first detectable seismic wave on the vertical component (usually the P or PKP phase), focal depth, magnitude, and geographic location. Magnitudes are usually the lowest of those determined by the Palisades, Berkeley, or Pasadena seismograph stations. Events which originated in the eastern United States are marked in the catalogue with double asterisks (**) which precede the geographic location.

Introduction

This work is designed to appeal to both the general public and research scientists who are interested in seismic activity that has been recorded in North Carolina. The first section contains a general description of the basic terminology used in earthquake seismology. The second part outlines the evolution of the catalogue of events recorded at seismograph station CHC which operated at Chapel Hill, North Carolina, from 1953 to 1970. The final section of this work is a catalogue of seismic events recorded at station CHC during the period January 1, 1955 to December 31, 1970.

Earthquake Terminology

An earthquake is usually a natural phenomenon that is indicative of the dynamic nature of the earth. On any given day thousands of earthquakes occur throughout the world, but fortunately most of them are small ones confined to unpopulated areas. The majority of these earthquakes go unnoticed by the public; however, earthquakes that affect populated areas oftentimes draw widespread attention. For example, the number of earthquakes recorded in the world during 1976 was essentially the same as in past years. But the number of major ones centered in populated areas was more than normal and a greater amount of property damage and loss of life resulted.

As in any science, earthquake seismology has some specific terms that need defining before we can proceed. An earthquake is the resultant vibration of the earth (both internal and on the surface) caused by the movement of seismic waves which radiate outward from a zone of sudden motion. The location of this movement is generally thought to be along a fault. The point of first motion is termed the earthquake focus or hypocenter (Fig. 1), which almost always lies at some depth. For convenience, seismologists define the epicenter as the point on the earth's surface that lies directly above the focus. The epicenter is the location that is commonly referred to as the position of an earthquake. The coordinates

listed for each event in the catalogue represent the epicenter for that particular event. The epicenter and the corresponding depth for an event determine its focus.

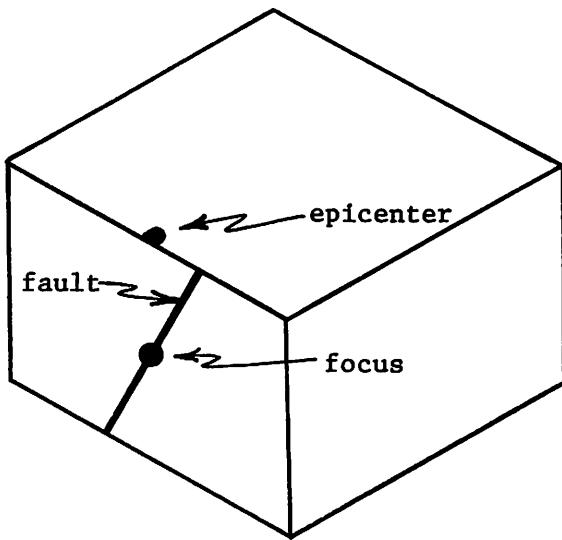

Fig. 1. Positions of the focus and epicenter of an earthquake caused by movement on an inclined fault.

The time separation between the P- and S-waves ($t_s - t_p$) on a seismogram permits us to determine the epicentral distance. Each seismograph station would determine this difference and then multiply it by an assumed velocity (v_o) for the medium through which the seismic wave traveled. This distance defines an arc of radius $v_o(t_s - t_p)$ on which the epicenter would lie. A combination of three such station calculations yields an intersection point or area which defines the epicenter. A minimum of four stations are required to determine the focus. Because inhomogeneities exist in the earth, the best epicenter determinations are obtained by using data available from seismograph stations close to the epicenter. Figure 2 shows the method of locating the epicenter of a hypothetical event in South Carolina from information recorded in Atlanta (ATL), Blacksburg (BLA), and Chapel Hill (CHC).

In addition to the location, the magnitude (M) of an earthquake is generally given, especially in those instances where the earthquake occurred near populated regions. The magnitude of an earthquake is based on the common logarithm of the maximum amplitude of the ground motion recorded at a seismograph station. Thus an earthquake with a magnitude of 6

would have ten times the ground motion of one having a magnitude of 5. This relationship was observed by the American seismologist, Charles F. Richter, in 1935. However, another American seismologist, Beno Gutenberg, did further research on magnitude scales and developed better methods of

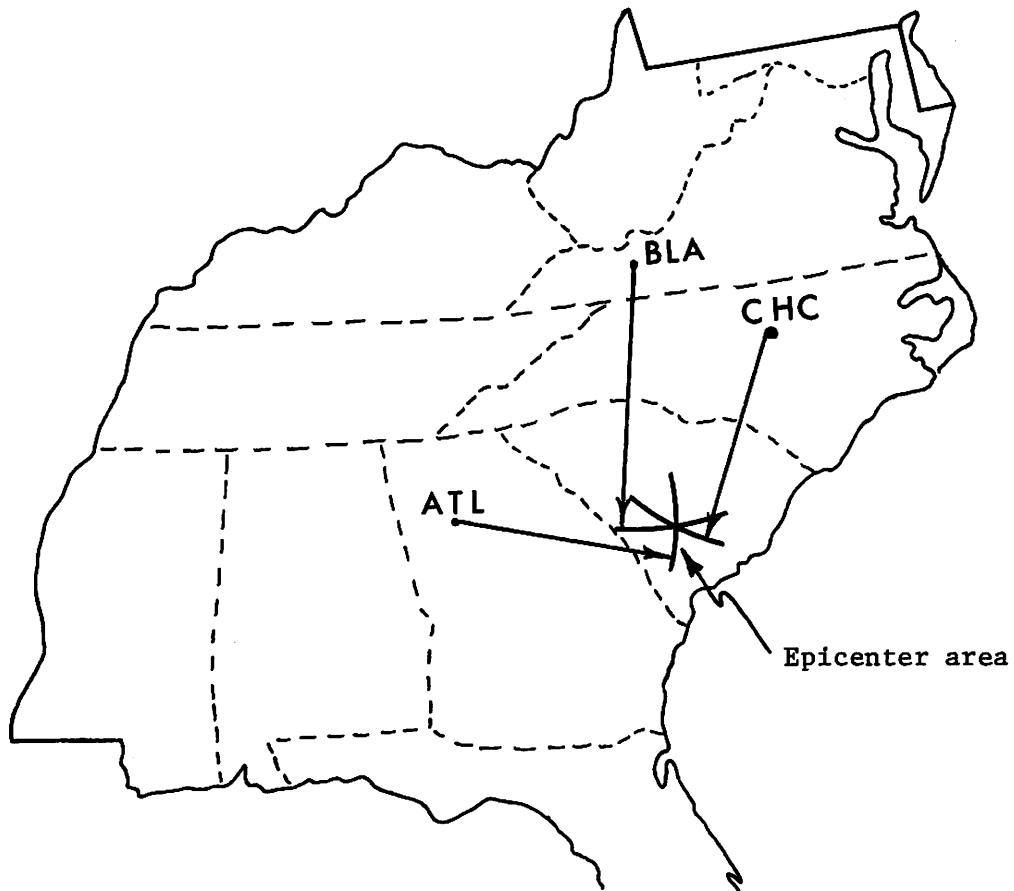

Fig. 2. Locating a hypothetical event from information recorded at Atlanta (ATL), Blacksburg (BLA), and Chapel Hill (CHC).

deriving magnitude values. It is important to note that the Richter or any other magnitude scale is open-ended. Thus there is no maximum value of 10 or 12 as is sometimes reported. The highest recorded magnitude was $M = 8.9$, which happened in Colombia in 1906 and in Japan in 1933 (Richter, 1958). Because of the logarithmic relationship of magnitude, it is possible to obtain negative magnitudes. Such values correspond to extremely small events.

Magnitude should not be confused with intensity, which is a subjective measure of actual ground motion and damage based on human assessments, whereas magnitude is the result of instrumental measurement.

Intensity is measured on a scale of I to XIII, as described by the Modified Mercalli Scale (Appendix I).

A more mathematical relationship does exist between magnitude and the amount of energy released by an earthquake. Table I shows this magnitude-energy relationship along with the approximate number of earthquakes in each magnitude range worldwide and corresponding intensity values. Note that energy is measured in ergs. In order to get a feel for how much energy an earthquake expends, consider that a 100-watt light bulb burning for one hour uses 3.6 trillion (3.6×10^{12}) ergs. This might sound like a large amount but you would need to burn that bulb 32 million years before it would use the energy expended in a few moments during the April 18, 1906 San Francisco earthquake ($M = 8.3$).

TABLE I. Worldwide earthquake statistics.

Intensity description of effects in populated areas	Approximate magnitude	Intensity range	Number of earthquakes per year	Energy (ergs)
Damage nearly total	>8.0	X - XII	0.1 - 0.2	$>10^{25}$
Great damage	≥ 7.4	IX - XI	4	$\geq 0.4 \times 10^{24}$
Serious damage	7.0 - 7.3	IX - X	15	$0.04-0.2 \times 10^{24}$
Considerable damage	6.2 - 6.9	VII - IX	100	$0.5-23 \times 10^{21}$
Slight damage	5.5 - 6.1	VI - VIII	500	$1-27 \times 10^{19}$
Felt by all	4.9 - 5.4	VI - VII	1,400	$3.6-57 \times 10^{17}$
Felt by many	4.3 - 4.8	V - VI	4,800	$1.3-27 \times 10^{16}$
Felt by some	3.5 - 4.2	III - V	30,000	$1.6-76 \times 10^{15}$
Not felt but recorded	2.0 - 3.4	II - IV	800,000	$4 \times 10^{10}-9 \times 10^{13}$

- Fig. 3. a. Benioff short-period seismometers
b. Teledyne Geotech portable seismometers
c. Recording drum for photographic seismograms
d. Recording drums for heat sensitive seismograms

Seismometers are instruments used to detect minute amounts of ground motion. Through the use of electronic amplifiers, the seemingly undetectable motion of many small events can be translated into the recorded motion of a pen or light beam onto paper. This movement is what seismologists measure in order to calculate magnitudes. Figures 3a and 3b show two generations of seismometers. The Benioff short-period seismometers (Fig. 3a) are rather massive and difficult to move in case the position of a station should need to be changed. In Fig. 3b we see the more portable Teledyne Geotech seismometers. Each of these has a mass of about 10 kg as opposed to about 175 kg for each of the Benioff instruments.

Figures 3c and 3d depict the recording devices used for the instruments in Fig. 3a and 3b, respectively. The single drum (Fig. 3c), which operated in a dark room, held three pieces of photographic recording paper. Light beams were deflected from mirrors in each of the galvanometers (background) which were wired to separate Benioff seismometers. After developing the photographic paper, any earthquake activity present would show up as seen in Fig. 4. The more modern recording drums are shown in Fig. 3d. These utilize heat sensitive paper and a heated stylus which actually burns a record of the ground motion onto the paper. This method of recording enables the drums to be visible while recording.

The recording seismic waves can be divided into three basic types (Fig. 5). The compressional or primary (P) wave, which includes regions of compression and dilation, is the first one to arrive. Particle motion is in the direction of propagation. P-waves are the fastest ones, having velocities between 6 and 8 kilometers per second. The second type of

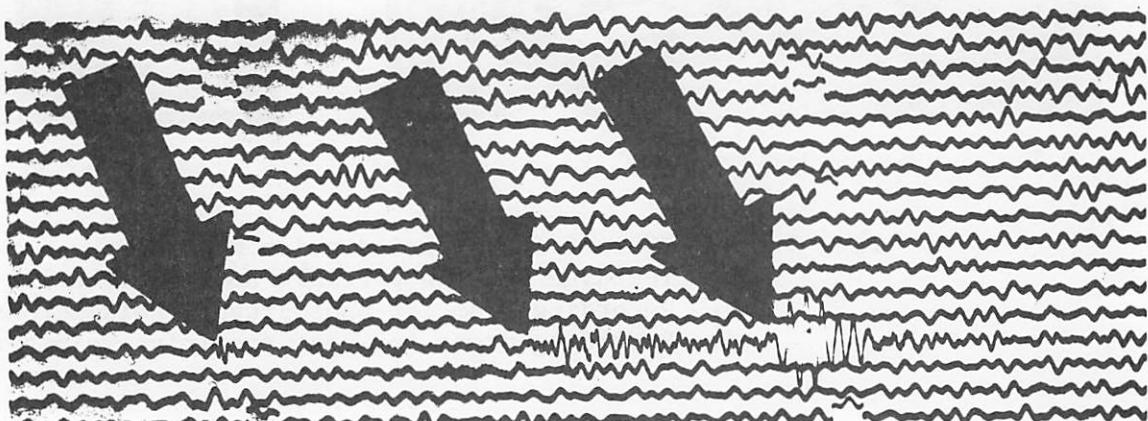

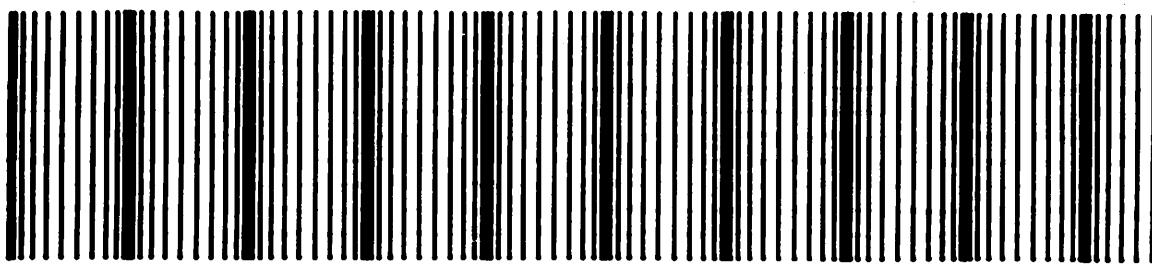

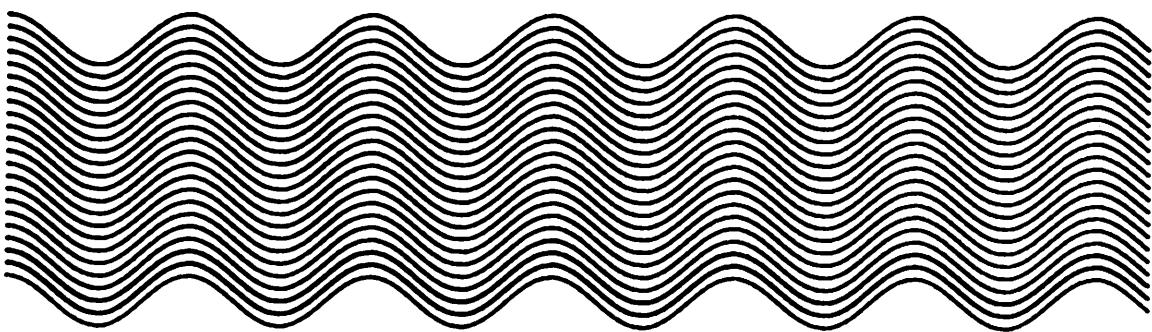

Fig. 4. Seismogram record of nearby event showing arrival of P, S, and LR waves.

Wave Motion

RAYLEIGH WAVE

Fig. 5. Three types of seismic waves.

wave is the shear wave, which is also called a secondary (S) wave because it is normally the second one to arrive. Velocities for S-waves are about 60% those of P-waves. As seen in Figure 5, particle motion is perpendicular to the direction of propagation. Whereas P- and S-waves travel through specific layers of the earth, the third type of seismic wave is confined to the outer surface. The longer period surface (L) waves are the slowest of the three types; hence they arrive much later than either the P- or S-waves. There are several types of surface waves but the only one we will mention is the Rayleigh wave (LR). Particle motion is described as elliptical retrograde, that is, particles move counterclockwise in the shape of an ellipse (Fig. 5).

Careful measurements of the velocities of the P- and S-waves enable seismologists to determine the earth's internal properties. In addition, a very important property of the S-wave is that it does not pass through liquids. This fact is the main reason geophysicists believe a portion of the earth's interior is liquid (Fig. 6). Examination of Figure 6 shows us that most of the initial arrivals at a recording station are either P or PKP phases. PKP is simply a P-wave that has penetrated the earth's core.

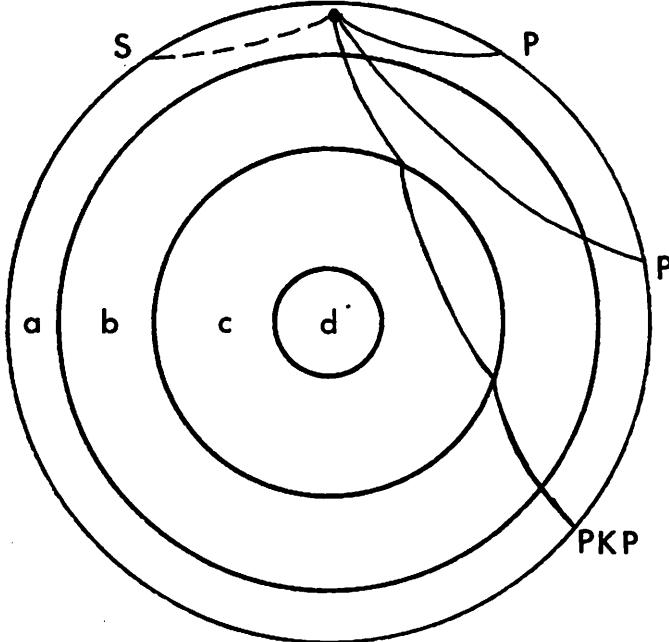

Fig. 6. Cross-sectional view of the layers of the earth and wave paths of P, PKP, and S waves from an earthquake; a = upper mantle; b = lower mantle; c = outer core; d = inner core.

As previously mentioned, most earthquakes are naturally occurring phenomena that are related to movement along faults. Other naturally occurring ones are related to volcanic activity, but these are usually small in number and size. There are cases where seismic energy is created by other means, thereby generating ground motion similar to that produced by the radiation of energy from a focal region. Table II lists examples of non-naturally occurring seismic disturbances taken from the catalogue.

TABLE II. Examples of non-naturally occurring seismic disturbances.

Type of seismic disturbance	Date	Origin Time	Location
Underground nuclear explosions	June 30, 1966	22:15:01	Nuclear Test Site, Nev.
	Oct. 27, 1966	05:57:58	Novaya Zemlya, U.S.S.R.
Mine explosion	Nov. 25, 1964	02:50:05	Coalwood, W. Va.
Ammunition detonation	July 29, 1966	04:36:25	Off east coast of U.S.

Evolution of the Catalogue

The Department of Geology at the University of North Carolina at Chapel Hill established a seismograph station (designation CHC) in March 1953, one of the few such stations located in the southeastern United States (see Fig. 7). This facility was under the supervision and guidance of Dr. Gerald R. MacCarthy, Professor of Geology at the University. Station operation was intermittent during the first 21 months of its existence due to numerous unforeseen problems. Therefore, good quality seismograms were not obtained until the early part of 1955.

Dr. MacCarthy personally ran the station for several years until graduate students began performing some of the routine tasks. Once the station was operating smoothly, Dr. MacCarthy started keeping a note card file of all seismic disturbances¹ which were detected at CHC. Utilizing

¹Seismic disturbances include earthquakes, nuclear blasts and other explosions (mining and ammunition).

United States Coast and Geodetic Survey (USC&GS) Preliminary Determination of Epicenter (PDE) cards and Monthly Listings, he compiled a list of over 2300 recorded events before he retired in 1965.

The authors realized the value of his efforts but some work had to be done to the compilation before obtaining any useful information. First, all seismograms for the period 1955 to 1970 were reexamined and Dr. MacCarthy's previous work verified. In addition, the card file was completed for the period March 1967 to December 1970, bringing the total number of recorded events to 3,040. Each event in the card file was entered on a computer card and a FORTRAN IV program was written to provide a chronological listing and a tabulation of events. Data cards were then checked against lists provided by the USC&GS PDE cards (1955-1964) and PDE Monthly Listings (1965-1970). Additional cross-checks were made with lists provided in the Seismological Notes, published in issues of the Bulletin of the Seismological Society of America, and United States Earthquakes, an annual publication of the National Oceanic and Atmospheric Administration. Springer and Kinnaman (1971) listed information concerning underground nuclear explosions which supplemented the above sources.

Events of particular interest were those which originated in the eastern United States. We define this area to be the continental United States east of the Mississippi River in addition to southeastern Missouri, which is included because of its high degree of seismicity. Each "local" event is designated by double asterisks (**) preceding its location description in the listing. In addition to the sources previously mentioned, the catalogues of McClain and Myers (1970) and Bollinger (1975) were consulted to insure complete coverage of events in the southeastern United States. A photographic catalogue of CHC seismograms of these events will be available in the near future.

Information contained on each data card includes the date, origin time of the event (rounded to the nearest second), latitude and longitude of the epicenter, arrival time at CHC, depth (in kilometers), magnitude, and geographic location. All times are Greenwich Mean Time (GMT). In the listing, if any of the preceding information is missing for an event, it was not provided by the sources or was indeterminable (in the case of arrival times). Origin times were rounded to the nearest second in order to conserve space on the data card and because early PDE listings (up to

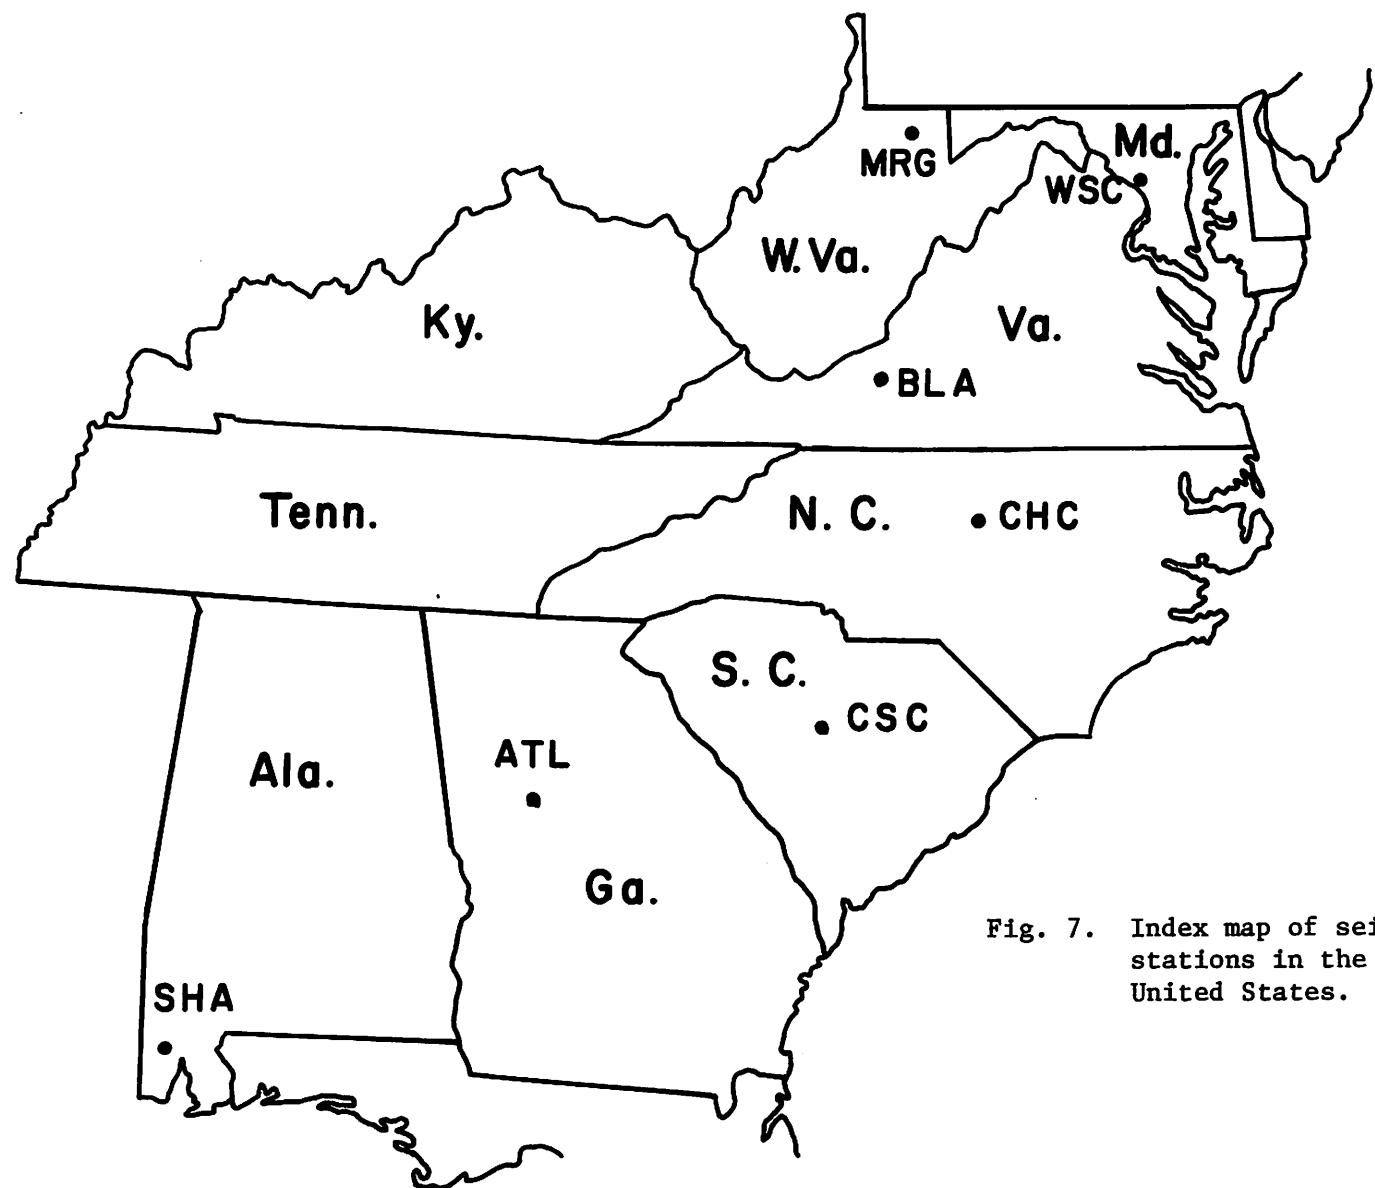

Fig. 7. Index map of seismograph stations in the southeastern United States.

August 1960) only provided origin times to the nearest second. Researchers who might use the data list should consult the original sources to obtain the accurate times. The absence of an arrival time indicates that either (1) the phase arrival was too emergent to assign a definite beginning point, or (2) too many concurrent arrivals obscured the initial motion of an arrival (e.g., during March 1957). The arrival times listed represent the first arrivals as recorded at CHC. Generally, this corresponds to either a P or PKP phase. However, first arrivals recorded for some events were later phases. The Jeffreys-Bullen (1958) travel-time tables should be consulted if one wishes to determine exactly which phases are indicated by the arrival times given. Times were read from the vertical (Z) component unless indicated otherwise by a N/S or E/W (north/south or east/west component, respectively) following the geographic location.

Magnitudes represent the lowest value by the Palisades (PAL), Berkeley (BRK), or Pasadena (PAS) seismograph stations. If none of these were available, the magnitude calculated by the USC&GS (CGS) was selected. However, in many instances the latter figure was considerably less than that determined by PAL, BRK, or PAS. Prior to 1966 magnitude determinations were about 0.7 units lower than those of most other stations (Bath, 1966).

Geographic locations are those given in the USC&GS PDE lists. The standardized naming scheme of Flinn and Engdahl (1965) was implemented in June 1965. When necessary, standard country abbreviations as listed in The World Book Atlas (1969) were used to limit the number of characters in the geographic location to 36. Compass direction abbreviations, such as N = north, NE = northeast, etc., were occasionally required for the same reason.

Seismograph station CHC ceased operations on December 31, 1970. A completely new station (designation CEH) began operating in August, 1975, under the auspices of the Department of Geology of the University of North Carolina at Chapel Hill. The location of station CEH is approximately five kilometers southwest of the former site of station CHC. The new equipment has resulted in better quality seismograms although the station operates at a lower gain due to increasing background noise associated with the cultural growth of Chapel Hill.

APPENDIX I. Modified Mercalli Scale (1956 Version)

The descriptions that follow for each level of intensity are modified from the version given by Richter (1958, p. 137-138), which presents an abridged form of the original Modified Mercalli Scale established by H. O. Wood and Frank Neumann in 1931.

As Richter pointed out, each effect is listed at that level of intensity at which it first appears frequently and characteristically. An effect may be found less strongly, or in fewer instances, at the next lower level; more strongly or more often at the next higher level. A few effects are listed at two successive levels to indicate a more gradual increase.

- I. Not felt; marginal and longer-period effects of large earthquakes, such as dizziness or nausea; swaying of trees, bodies of water.
- II. Felt by persons at rest, on upper floors, or favorably placed.
- III. Felt indoors; hanging objects swing; vibration similar to that produced by the passing of light trucks; may not be recognized as an earthquake.
- IV. Hanging objects swing; vibration similar to that produced by the passing of heavy trucks; standing cars rock; windows, dishes, doors rattle; glassware clinks.
- V. Felt outdoors; sleepers wakened; liquids disturbed, some spilled; small unstable objects displaced or upset; doors swing; shutters, pictures move; pendulum clocks stop, start, change rate of motion.
- VI. Felt by all; many frightened and run outdoors; persons walk unsteadily; windows, dishes, glassware broken; objects thrown from shelves; pictures fall off walls; furniture moved or overturned; small bells ring; trees, bushes shaken; weak plaster, poor mortar crack.
- VII. Difficult to stand; noticed by drivers of automobiles; hanging objects quiver; furniture broken; weak chimneys broken at roof line; poor masonry cracks; loose bricks, plaster, stones, tiles, cornices fall; small slides and caving in along sand and gravel banks; large bells ring.
- VIII. Steering of automobiles affected; damage to non-reinforced masonry with partial collapse; falling of stucco and some masonry walls; chimneys, factory stacks, monuments, towers, elevated tanks twist and fall; frame houses, if not bolted down, shift on foundations; loose panel walls thrown out; decayed piling broken off; tree branches broken; changes in flow and temperature of wells and springs; cracks formed in wet ground and steep slopes.

- IX. General panic; poor masonry destroyed; unbraced masonry heavily damaged; reinforced masonry seriously damaged; general damage to foundations; frame structures, if not bolted down, shift off foundations; serious damage to reservoirs; underground pipes broken; conspicuous cracks in ground; in alluvial areas sand and mud ejected; earthquake fountains and sand craters developed.
- X. Most masonry and frame structures destroyed; some well-built wooden structures and bridges destroyed; serious damage to dams, dikes, embankments; large landslides; water thrown on banks of canals, rivers, lakes; sand and mud shifted horizontally on beaches and flat land; rails bent slightly.
- XI. Rails bent greatly; underground pipelines completely out of service.
- XII. Damage nearly total; large rock masses displaced; lines of sight and level distorted; objects thrown into the air.
