

**FISHERY MANAGEMENT PLAN UPDATE
AMERICAN SHAD
AUGUST 2025**

STATUS OF THE FISHERY MANAGEMENT PLAN

Fishery Management Plan History

| | | |
|-----------------------|----------------------|---------------|
| FMP Documentation: | October 1985 | |
| | Amendment 1 | April 1999 |
| | Technical Addendum 1 | February 2000 |
| | Addendum I | August 2002 |
| | Amendment 3 | February 2010 |
| Supplements: | Supplement | October 1988 |
| Comprehensive Review: | To be determined | |

The first Atlantic States Marine Fisheries Commission (ASMFC) Fishery Management Plan (FMP) for Shad and River Herrings was adopted in 1985. The FMP did not require any specific management approach or monitoring programs within the management unit, asking only that states provide annual summaries of restoration efforts and ocean fishery activity. It specified four management objectives: regulate exploitation, improve habitat accessibility and quality, initiate programs to introduce alosine stocks into historic waters, and recommend and support research programs. The 1988 Supplement (ASMFC 1988) reassessed the research priorities identified in the original 1985 plan and created a new listing of research priorities.

Amendment 1 (ASMFC 1999) reported that the majority of American shad (*Alosa sapidissima*) stocks were not overfished, but almost all were believed to be at or near historically low levels. Therefore, Amendment 1 required increased annual reporting requirements on juveniles, adult spawning stocks, annual fishing mortality, and habitat. A fishing mortality threshold (overfishing) was defined as a reference point of F_{30} . A fishing mortality rate of F_{30} will result in 30% of the maximum spawning potential in the female component of an unfished population. Amendment 1 also implemented the phase-out of the ocean intercept fishery for American shad (effective in 2005). Eliminating the North Carolina ocean intercept fishery was important to controlling harvest to specific river origins.

Technical Addendum 1 (ASMFC 2000) modified several technical errors and provided clarification of several monitoring requirements in Amendment 1.

Addendum I (ASMFC 2002) changed the conditions for marking hatchery-reared alosines. The addendum clarifies the definition and intent of de minimis status for the American shad fishery. It also further modifies and clarifies the fishery-independent and fishery-dependent monitoring requirements of Technical Addendum 1.

The ASMFC coastwide stock assessment completed in 2007 found that American shad stocks were at all-time lows and did not appear to be recovering to acceptable levels. Therefore, under ASMFC's Amendment 3 to the Interstate FMP for Shad and River Herring, individual states were required to develop Implementation Plans (ASMFC 2010). Implementation Plans consisted of two parts: 1. Review and update of the fishing/recovery plans required under Amendment 1 for the stocks within their jurisdiction; and 2. Habitat plans. North Carolina submitted fishing/recovery plans that meet the requirements of Amendment 3, known as the North Carolina American Shad Sustainable Fishery Management Plan (SFMP) (NCDMF 2011, NCDMF 2017, and NCDMF 2023). North Carolina submitted habitat plans that meet the requirements of Amendment 3, known as the North Carolina American Shad Habitat Plan (NCDMF 2014 and NCDMF 2020).

To ensure compliance with interstate requirements, North Carolina also manages this species under the North Carolina Fishery Management Plan for Interjurisdictional Fisheries (IJ FMP). The goal of the IJ FMP is to adopt fishery management plans, consistent with N.C. law, approved by the Mid-Atlantic Fishery Management Council, South Atlantic Fishery Management Council, or the ASMFC by reference and implement corresponding fishery regulations in North Carolina to provide compliance or compatibility with approved fishery management plans and amendments, now and in the future. The goal of these plans, established under the Magnuson-Stevens Fishery Conservation and Management Act (federal council plans) and the Atlantic Coastal Fisheries Cooperative Management Act (ASMFC plans) are like the goals of the Fisheries Reform Act of 1997 to “ensure long-term viability” of these fisheries (NCDMF 2015).

Management Unit

The management units for American shad are all the migratory American shad stocks of the Atlantic coast of the United States. American shad and hickory shad management authority lies with the ASMFC and is coordinated by Atlantic coastal states from Maine through Florida through approved Sustainable Fishery Management Plans for American Shad. Responsibility for management action in the Economic Exclusive Zone (EEZ), located from three to 200 miles from shore, lies with the Secretary of Commerce through the Atlantic Coastal Fisheries Cooperative Management Act (ACFCMA) in the absence of a federal FMP.

Goal and Objectives

Migratory stocks of American shad have been managed under the ASMFC since 1985. These species are currently managed under Amendment 3 (American shad) and Amendment 1 (American and hickory shad (*Alosa mediocris*) to the ASMFC FMP, Technical Addendum 1, and Addendum I. Because of the scarcity of data on hickory shad populations, the ASMFC member states decided to focus Amendment I on American shad regulations and monitoring programs. However, the amendment requires states to initiate fishery-dependent monitoring programs for hickory shad while recommending continuance of current fishery-independent programs for these species. The goal of Amendment 3 is to protect, enhance, and restore Atlantic coast migratory stocks and critical habitat of American shad in order to achieve levels of spawning stock biomass that are sustainable, can produce a harvestable surplus, and are robust enough to withstand unforeseen threats. To achieve this goal, the plan adopts the following objectives:

- Maximize the number of juvenile recruits emigrating from freshwater stock complexes.
- Restore and maintain spawning stock biomass and age structure to achieve maximum juvenile recruitment.
- Manage for an optimum yield harvest level that will not compromise Objectives 1 and 2.
- Maximize cost effectiveness to the local, state, and federal governments, and the ASMFC associated with achieving Objectives 1 through 3.

DESCRIPTION OF THE STOCK

Biological Profile

American shad are anadromous fish, meaning they spend most of their adult lives at sea, only returning to freshwater in the spring to spawn. Shad young leave their home river within the first year and will spend the next few years at sea, schooling in large numbers with shad from other regions and feeding on plankton, small fish, and crustaceans. Upon reaching maturity, at about age 4, they return to the streams in which they were born to spawn. Males or "buck shad" return first, followed by females or "roe shad." They spawn usually at night or during overcast days. In the southern range (Cape Fear River to Florida), females release as many as 700,000 eggs during the spawning season, but both males and females normally die after spawning. In the northern range, females typically release 300,000 eggs or less during the spawning season; however, most shad will return to spawn in the following years, with some shad living up to 10 years.

Stock Status

The most recent coastwide stock assessment of American shad stated that populations in the Albemarle Sound, including Roanoke River, are sustainable and not depleted, whereas a determination of stock status could not be assigned for the Tar-Pamlico, Neuse, and Cape Fear rivers due to limited information (ASMFC 2020).

Stock Assessment

The 2020 American shad benchmark stock assessment found coastwide populations of American shad to be depleted. Factors such as overfishing, inadequate fish passage at dams, predation, pollution, water withdrawals, channelization of rivers, changing ocean conditions, and climate change are likely responsible for the decline from historic shad abundance levels. The assessment found that American shad recovery is limited by restricted access to spawning habitat, with 40% of historic habitat in the U.S. and Canada currently blocked by dams and other barriers possibly equating to a loss of more than a third of spawning adults. The abundance of American shad relative to historic levels is unknown for most systems but was determined to be depleted for the Potomac River and Hudson River, and not depleted for the Albemarle Sound. Coastwide adult mortality is largely unknown and juvenile mortality status cannot be determined due to insufficient data collection. The stock assessment chose to use the ‘depleted’ determination instead of ‘overfished’ because of the impact of fishing on American shad stocks cannot be separated from all other factors that impact abundance. The status for adult mortality rate and abundance could not be determined for the Tar-Pamlico and Cape Fear rivers. The Neuse River adult mortality rate was found to be sustainable (ASMFC 2020). The 2020 benchmark assessment for American shad was endorsed by the Peer Review Panel and accepted by the ASMFC Shad and River Herring Board for management use in August 2020. The ASMFC has not conducted a coastwide assessment of hickory shad.

DESCRIPTION OF THE FISHERY

Current Regulations

The MFC enacted a rule in 1995, which established a closed season for American shad and hickory shad. It is unlawful to take these species by any method except hook-and-line April 15–December 31. The ocean intercept fishery for American shad was closed to all harvest January 1, 2005 (ASMFC 2002).

In the Albemarle, Croatan, Roanoke, and Currituck sounds and tributaries (Albemarle Sound Management Area; ASMA), floating gill nets of 5.25-inch stretch mesh (ISM) to 6.5 ISM, were limited to 500 yards, could only be utilized from March 2 through March 17, and must be fished at least once during a 24-hour period (no later than noon each day; M-5-2023). A portion of the Albemarle Sound from the lower Chowan River to the western Albemarle Sound was closed to the use of all gill nets. The area closure was implemented to prolong the striped bass quota by reducing gear in hot spot areas, which also impacted harvest for American shad. The closing date for this gear occurred when the ASMA striped bass harvest quota was met to prevent additional striped bass discards. While American shad could still be harvested using other commercial gears February 15 through April 14, 2023, the gill net gear restriction, coupled with the area closure, had an impact on harvest for the remainder of the open commercial season for American shad.

The western portion of Albemarle Sound near the mouth of the Roanoke River (including Roanoke, Cashie, Middle and Eastmost Rivers) is closed to gill netting year-round. Gill nets with a mesh length of 3.25–4.0 ISM could not exceed 800 yards and were allowed from January 1 through April 30, 2023 (M-2-2023). Attendance for fixed or stationary small mesh gill nets (3.0–3.75 ISM) was required September 1–November 30 when the area reopened to this gear (M-10-2023). The ASMA was closed to all other gill nets except for 3.0–4.0 ISM run-around, strike, drop, and drift gill nets until the area was opened for estuarine flounder season on October 2, 2023 (M-16-2023). During the 2023 estuarine flounder season, the ASMA

was open to gill nets configured for flounder, single overnight soaks, Monday night through Thursday morning until the commercial quota for this area was met and gear removed on October 21 (M-21-2023).

Since May 2016, in other areas outside of the ASMA (excluding the Cape Fear River), a statewide rule limits the amount of large mesh (4.0-inch and greater) gill net set in internal Coastal Fishing Waters to no more than 1,500 yards per vessel (M-4-2023). A prior version of the rule (3,000 yards maximum) was suspended for most internal Coastal waters as a result of sea turtle conservation measures to institute no more than 2,000 yards per vessel of 4.0–6.5-inch gill net in the Tar-Pamlico and Neuse rivers systems in earlier years. Additionally, in certain sections of the Tar-Pamlico and Neuse rivers, gill nets with a mesh size less than five inches must be attended at all times. Also, it is unlawful to use any gill nets in Joint Fishing Waters from midnight on Friday to midnight on Sunday each week (except for portions of Albemarle and Currituck sounds). These existing gill net measures have likely reduced American shad harvest since they have remained in effect since the spring 2012 fishing season and remain in effect indefinitely.

In the Cape Fear River there are different gill net restrictions than described above for the Tar-Pamlico and Neuse river systems (i.e., mesh lengths, spacing, set/retrieval days and times). Large mesh gill nets (4.0–6.5-inch) are prohibited in the Cape Fear River (north of the Railroad Bridge) and Northeast Cape Fear River (north of I-40 bridge) north of Wilmington, NC. Run-around, strike, drop, drift, and trammel gill net commercial operations are limited to 800 yards per commercial fishing operation (M-5-2023). It is unlawful to use gill nets of any mesh size on weekends in the Cape Fear system. This measure will remain in effect indefinitely.

A management response for striped bass has been in effect since March 18, 2019, prohibiting the use of all gill nets upstream of the ferry lines from the Bayview to Aurora ferry in the Tar-Pamlico River and the Minnesott Beach and Cherry Branch ferry in the Neuse River (Proclamation M-6-2019). This prohibition directed by the N.C. Marine Fisheries Commission was in response to Supplement A to Amendment 1 to the N.C. Estuarine Striped Bass FMP, and was intended to reduce striped bass fishing mortality, and has essentially protected American shad as well by removing gill nets from the normal fishing grounds for American shad in the Tar-Pamlico River.

At its August 2022 business meeting, the MFC approved Notice of Text for Rulemaking to begin the process to amend the Mutilated Finfish Rule (15A NCAC 03M .0101). The amended rule would provide flexibility to manage variable conditions for the use of finfish, including hickory shad, as cut bait by simplifying the rule such that only species subject to a possession limit are subject to the requirements unless otherwise specified in a MFC rule or a proclamation issued under the authority of a MFC rule. The MFC gave final approval of the rule at its February 2023 business meeting and the rule was scheduled to be reviewed for final approval by the Rules Review Commission (RRC) in June 2023.

At its June 15, 2023, meeting, the RRC objected to the Mutilated Finfish Rule in accordance with N.C.G.S. § 150B-21.10. At its August 25, 2023, business meeting, the MFC moved to keep the mutilated finfish rule as it was originally and grant proclamation authority to the Fisheries Director as Item (4) in the rule to add exemptions for other species. Following its October 5, 2023, special meeting, the RRC returned the mutilated finfish rule to the MFC in accordance with Session Law 2023-134, Section 21.2(m). Since the returned rule was a proposed amendment at the June 15, 2023, meeting, and the objection was not to existing language, there was no change to the N.C. Administrative Code. The mutilated finfish rule remains in force as readopted effective April 1, 2019.

Commercial Fishery

North Carolina's commercial landings in 2024 were 25,624 pounds (Table 1; Figure 1). Anchored gill nets configured for harvesting American shad were prohibited in the ASMA effective March 17, 2023, due to the ASMA striped bass commercial quota being met (Proclamation M-6-2023). While American shad could

still be landed commercially until April 14, 2024, anchored gill nets are the primary gear used for shad in the ASMA and the gear and area restriction did have an impact on landings.

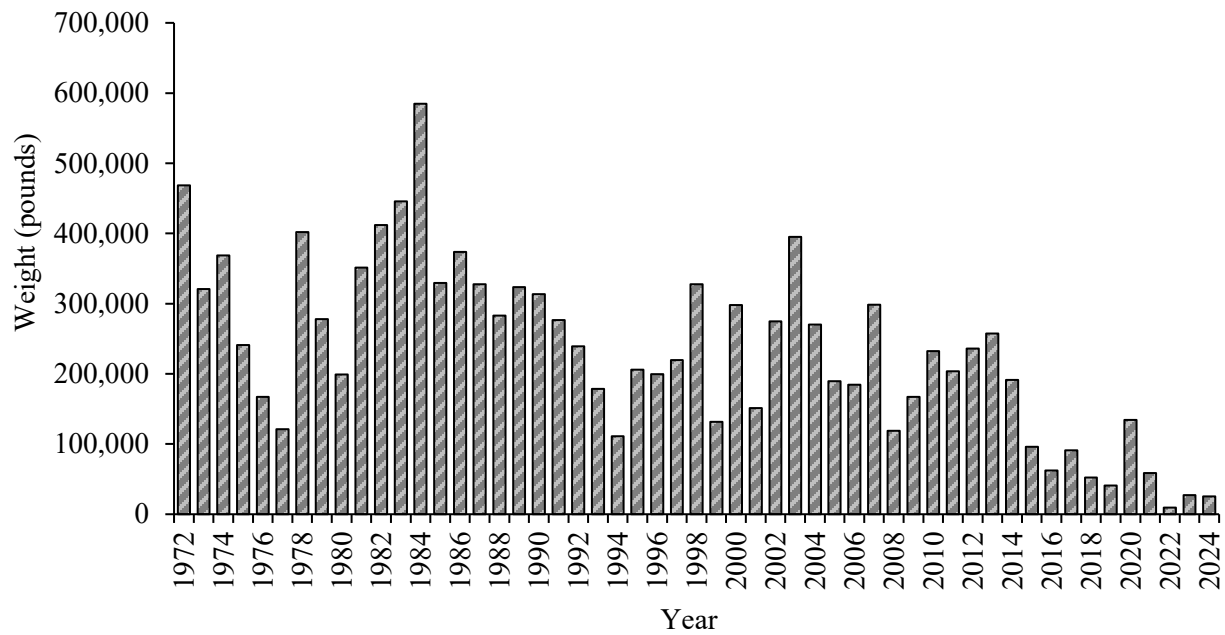

Figure 1. Commercial harvest (weight in pounds) of American shad from North Carolina, 1972–2024.

Table 1. Commercial harvest (weight in pounds) of American shad from North Carolina, 1972–2024. Commercial harvest from the Atlantic Ocean has been prohibited since 2007.

| 1998 | 327,556 | | |
| | | Mean | 231,478 |

Overall, landings show a decreasing trend until 2013 when average landings leveled off with the implementation of the American Shad SFMP. Commercial harvest is sporadic and cyclical and annual trends show these changes. Figure 2 describes the landings break down by the four areas of the state, as stated in the American Shad SFMP. The Albemarle Sound area accounted for approximately 89% of total state landings in 2024.

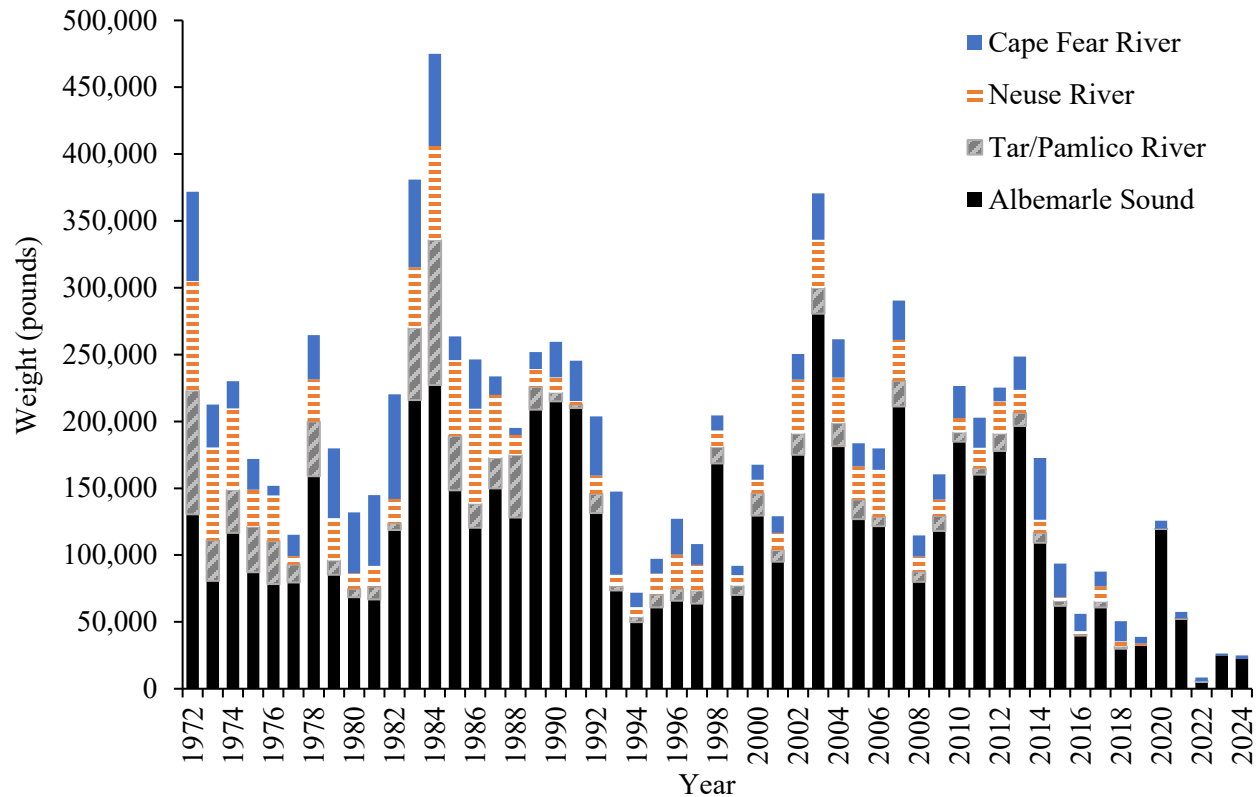

Figure 2. Commercial harvest (weight in pounds) of American shad from North Carolina by major waterbody, 1972–2024.

Recreational Fishery

Recreational fishing activity is monitored through coordination with the North Carolina Wildlife Resources Commission (WRC) and the DMF. Methods were developed to conduct recreational creel surveys on the Roanoke, Tar-Pamlico, and Neuse rivers starting in 2012, and for the Cape Fear River in 2013. Recreational landings for American shad are minimal throughout the Albemarle Sound-Roanoke River due to limited to no effort focused on American shad in this system. The bulk of the North Carolina recreational fishery occurs in the Cape Fear River system where substantial effort is targeted on American shad with an estimated harvest of 1,141 fish in 2024 (Table 2).

Table 2. Recreational harvest (number of fish landed and weight in pounds) and releases (number of fish) and commercial harvest (weight in pounds) of American shad from the North Carolina Central Southern Management Area (CSMA), 2012–2024.

MONITORING PROGRAM DATA

Fishery-Dependent Monitoring

Commercial fishing activity is monitored through fishery-dependent sampling conducted by the DMF since 1972, with a sampling gap during 1994–2000 due to lack of funding. Data collected in this program allow the size and age distribution of American Shad to be characterized by sex (female and male). The predominant fishery for American shad is estuarine gill nets and harvest is primarily focused on female American Shad, as they are harvested for their roe (eggs). In 2024, gill nets accounted for greater than 89% of the commercial landings. A total of 81 females and 30 males were measured from the commercial fishery in 2024 (Tables 3 and 4). The average size was 17 inches fork length for female and 15 inches fork length for male American shad (Figures 3 and 4).

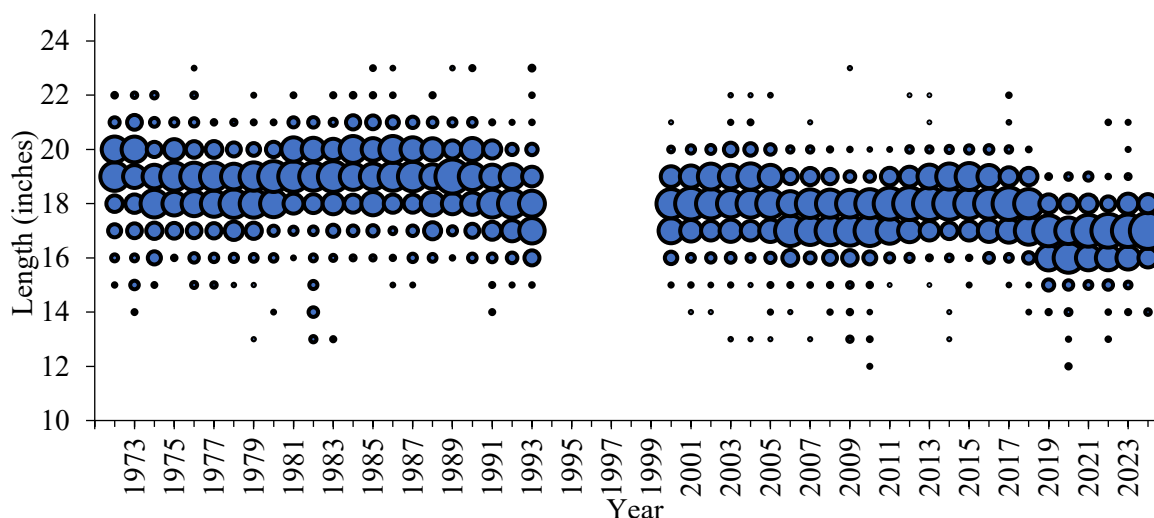

Figure 3. Commercial length frequency (fork length, inches) of female American shad harvested, 1972–2024. Bubbles represent fish at length and the bubble size is proportional to the number of fish at that length.

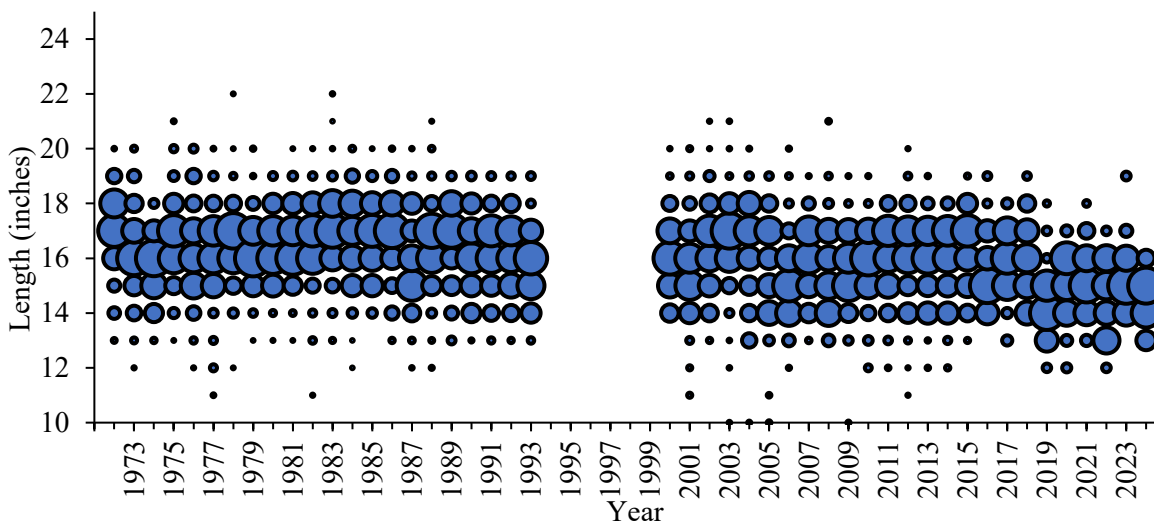

Figure 4. Commercial length frequency (fork length, inches) of male American shad, 1972–2024. Bubbles represent fish at length and the bubble size is proportional to the number of fish at that length.

Table 3. Mean, minimum, and maximum lengths (fork length, inches) of female American shad measured from the commercial fisheries, 1972–2024.

| Year | Mean Length | Minimum Length | Maximum Length | Total Number Measured |

Figure 5 and Figure 6 illustrate the American Shad length at age (mean, minimum, and maximum) for females and males from all age samples collected at any given age from 1972 to 2022. Age data for 2023 and 2024 are incomplete and will be provided when aging is complete.

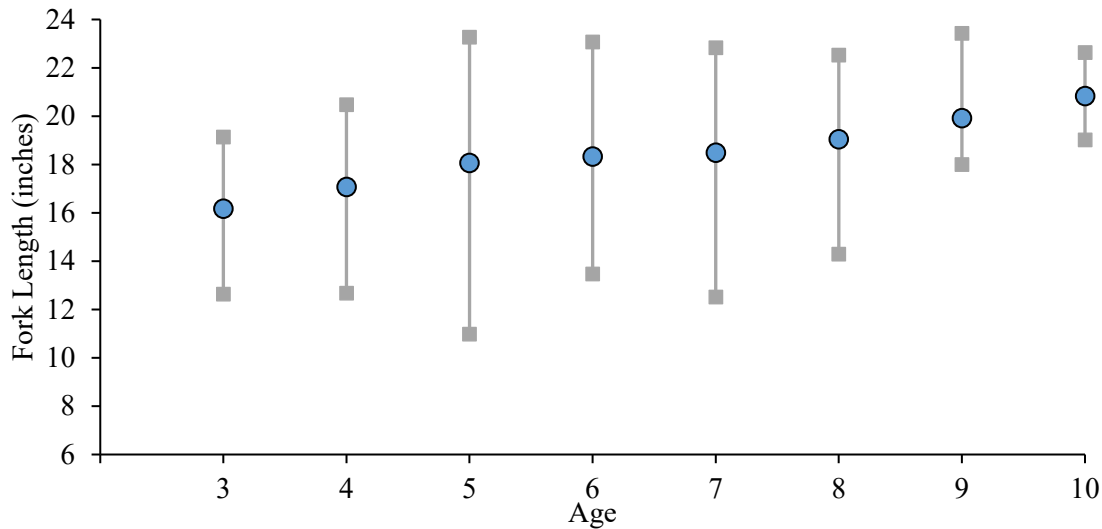

Figure 5. Female American shad length at age from all age samples collected from fishery-dependent monitoring, 1972–2022. Blue circles represent the mean size at a given age while the grey squares represent the minimum and maximum observed size for each age. Age data unavailable for 2023–2024.

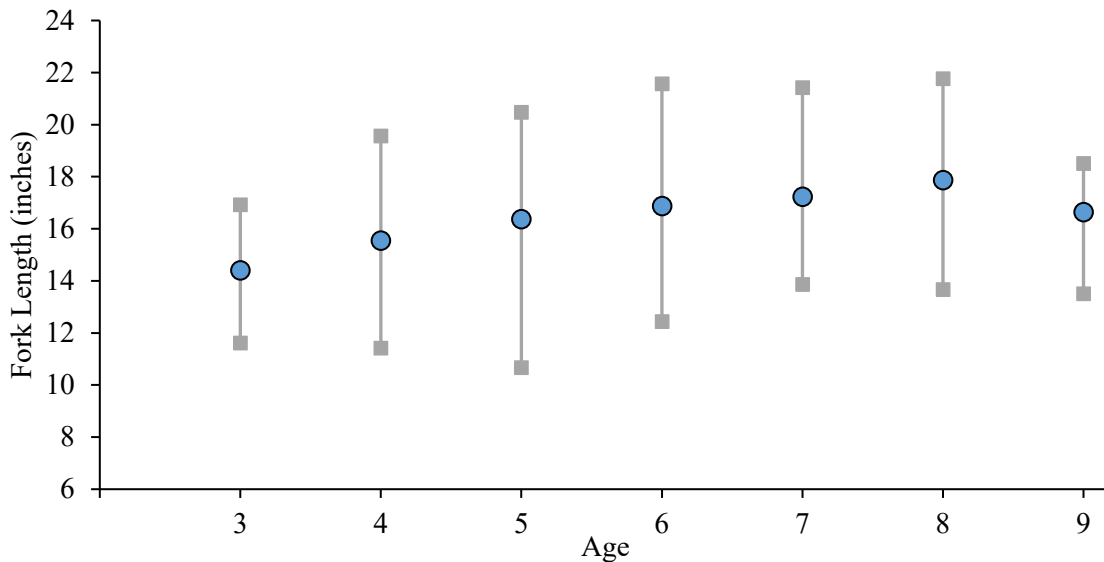

Figure 6. Male American shad length at age from all age samples collected from fishery-dependent monitoring, 1972–2022. Blue circles represent the mean size at a given age while the grey squares represent the minimum and maximum observed size for each age. Age data unavailable for 2023–2024.

Fishery-Independent Monitoring

The DMF does not have a dedicated juvenile (age 0) survey for American Shad but conducts two juvenile beach seine surveys in the Albemarle Sound area, Juvenile Anadromous Survey (Program 100). Although the surveys were designed to monitor river herring [blueback herring (*Alosa aestivalis*) and alewife (*Alosa pseudoharengus*)] and striped bass, both surveys capture American shad. The river herring beach seine survey has been conducted in the Chowan River and Albemarle Sound area to monitor Blueback Herring and Alewife abundance since 1972. The survey established 11 stations in the near-shore nursery areas of the Chowan River and Albemarle Sound, sampled twice a month. The striped bass beach seine survey has

been conducted in the western Albemarle Sound to monitor juvenile striped bass since 1993. The survey established nine stations in the near-shore nursery areas of the western Albemarle Sound, where early-stage juvenile striped bass would be settling after larval metamorphosis from spawning grounds on the Roanoke River. The stations are sampled once a week, for six weeks (starting the first week in June). American shad captured are recorded but not consistently until 1995. Following the six weeks of sampling, the stations are sampled bimonthly through October.

The ASMFC 2007 benchmark assessment for American Shad only considered the juvenile river herring beach seine survey data for a relative abundance index for American Shad. Due to the consistently low level of catch since 1972, the authors felt that the survey did not adequately reflect the true abundance of juvenile American Shad and should not be used for management. During the ASMFC 2020 benchmark stock assessment for American Shad a combination of seine stations from the river herring survey (five stations) and the striped bass survey (nine stations), all samples June through October, were selected to determine a juvenile abundance starting in 1996 (zero catches in 1995). A Zero-inflated Negative Binomial GLM model was determined as the best recommended predictions of relative annual abundance. Water temperature, salinity, month and cloud cover were all shown to significantly impact catch rates and presence. The best performing model was $\text{Counts} \sim \text{Year} + \text{water temperature} + \text{salinity} | \text{salinity} + \text{cloud cover} + \text{month}$. Updates to annual trends in abundance are illustrated in Figure 7 as arithmetic mean, in lieu of updating the model annually. The relative abundance for 2024 was 1.27 (American Shad per tow) which is an increase from the 2023 relative abundance of zero (American Shad per tow).

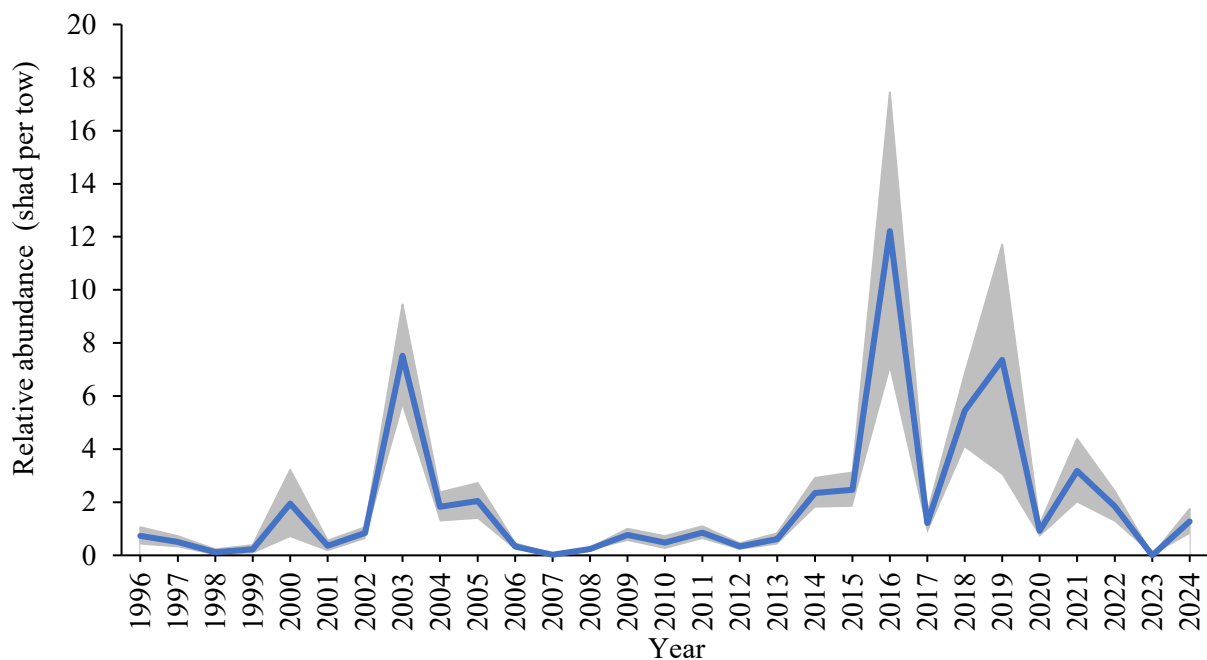

Figure 7. Relative abundance index (fish per tow) of American shad collected from Program 100 in Albemarle Sound during June through October 1996–2024. Error bars represent ± 1 standard error.

Adult American shad are monitored using the DMF Albemarle Sound Independent Gill Net Survey (Program 135) and WRC electrofishing surveys to estimate female relative abundance and relative fishing mortality in the Albemarle Sound-Roanoke River area. In other areas of the state, WRC conducts electrofishing surveys to estimate abundance and the relative fishing mortality. These data are incorporated into the North Carolina SFMP for American Shad described in more detail in the Management Strategy section.

Program 135 began collecting biological data on adult American Shad in 2000, sex was not recorded until 2004. The survey uses a stratified random sampling scheme designed to characterize the size and age distribution for key estuarine species in the Albemarle Sound. American Shad intercepted by DMF gill net surveys outside to the Albemarle Sound-Roanoke River area are reported annually to the ASMFC, due to low numbers of catch relative abundance is not estimated.

Program 135 was suspended in February 2020 due to COVID-19 restrictions and protected species interactions. The survey resumed in the fall of 2021. In November 2021, the Albemarle Sound Independent Gill Net Survey (IGNS) expanded from six to eight zones and reduced soak time from 24-hours to 12-hours. Additionally, in March 2022, sink gill nets were removed from the survey, reducing effort to 480 yards per set (12 units of effort). Additional zones were added to meet DMF research priorities to expand the spatial coverage of the survey. Soak times were reduced and sink nets were removed to reduce interactions with endangered species through ongoing consultation with the United States Fish and Wildlife Service (USFWS) and the National Oceanic and Atmospheric Association (NOAA Fisheries). It should be noted that with such a major change in survey design, the index derived from this survey starting in November 2021 will not be directly comparable to the prior historical time series. When calculating female relative abundance using historical IGNS data, all sink gill nets were removed. It is important to note that most American shad intercepted in the IGNS survey are from float gill nets. Therefore, the removal of sink gill nets from the data set did not significantly impact the relative abundance estimates of American shad from the survey.

The female index of abundance for American shad from Program 135 uses the January through May catch of female American shad from float nets in the western Albemarle Sound. For 2024, the female index of abundance for American shad was 0.079 fish per net (Figure 8). Due to the survey suspension index values are not available for 2020 and 2021.

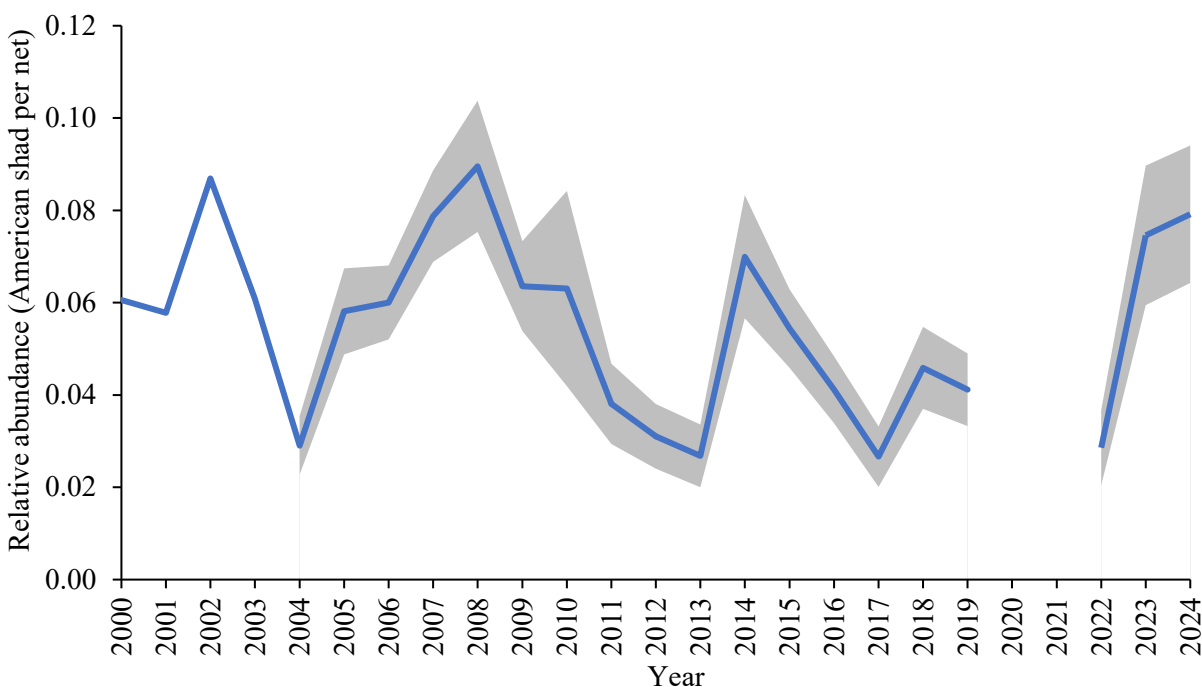

Figure 8. Relative abundance index of female American shad (fish per net, all float net mesh sizes) collected from Program 135 in Albemarle Sound during January through May 2000–2024. Error bars represent ± 1 standard error. * Survey suspended February 20, 2020, and did not resume until fall 2021.

A total of 201 females and 177 males were measured from the DMF fishery-independent monitoring (Tables 6 and 7) from all areas of the state. The average size of female American Shad is 16 inches fork length and male are 14 inches fork length.

Table 6. Mean, minimum, and maximum lengths (fork length, inches) of female American shad measured from DMF fishery-independent sampling programs, 2000–2024.

Blue circles represent the mean size at a given age while the grey squares represent the minimum and maximum observed size for each age. Age data unavailable for 2024.

RESEARCH NEEDS

On an annual basis the ASMFC publishes a prioritized list of short term and long-term research needs for American shad and river herring in the Review of the Atlantic States Marine Fisheries Commission Fishery Management Plan for Shad and River Herring (ASMFC 2020).

For more information on research needs for River herring please see: https://asmfc.org/uploads/file/653bf9e9ShadRiverHerringFMP_ReviewFY2022.pdf

MANAGEMENT

Shad are managed under Amendment 3 to the ASMFC Interstate FMP for Shad and River Herring. The Amendment requires states and jurisdictions to develop sustainable fishery management plans, which are reviewed by the ASMFC Technical Committee and approved by the ASMFC Shad and Herring Management Board, in order to maintain commercial and recreational fisheries past January 2013. The ASMFC requires that these plans be re-evaluated every five years to update and modify sustainable management measures. The first NC American Shad SFMP, effective in 2013 through 2017, identified sustainability parameters for four regions of the state: Albemarle-Roanoke River, Tar-Pamlico, Neuse, and Cape Fear River systems. Sustainability parameters are based on the female portion of the stock because the commercial fishery targets roe shad; roe landings can account for as much as 90% of the total American shad landings in a year. The second NC American Shad SFMP, approved October 2017 for 2018 through 2022, maintained the original sustainability parameters of relative fishing mortality (F) and abundance indices, but relative F will now be computed by dividing commercial landings by a hind cast 3-year average of a survey index. The previous plan used a centered 3-year average.

The third NC American Shad SFMP, approved January 2023 for 2023 through 2027 added a sustainability parameter for juvenile abundance in the Albemarle Sound-Roanoke River and updated female relative F parameters to include the commercial and recreational harvest for the Tar-Pamlico, Neuse, and Cape Fear river systems. Previously, relative F was computed for these systems using only information from the commercial harvest of roes (females), in pounds of fish. Commercial harvest of American shad has continued to decline due to management regulations and reduced participation in the fishery in these areas. The addition of recreational data to the relative F calculation has shortened the time-series, but the estimates are more informative of total removals from the Tar-Pamlico, Neuse, and Cape Fear river systems. Thresholds have been established for indices in each system to define levels needed to reduce mortality and avoid diminishing potential stock reproduction and recruitment. Thresholds for sustainability parameters are fixed using available survey data through 2022 and will remain fixed during the next 5-year management period.

Albemarle Sound-Roanoke River

The Albemarle Sound-Roanoke River system has four sustainability parameters: juvenile abundance, female CPUE based on the DMF Albemarle Sound Independent Gill Net Survey (IGNS, Program 135), female CPUE based on the WRC electrofishing survey, and female relative fishing mortality (F) computed by dividing commercial landings by a hind cast 3-year average of the DMF IGNS index. As written in the 2023 SFMP, exceeding the juvenile abundance, female CPUE based on Albemarle Sound IGNS or the female relative F parameters for three consecutive years will trigger management action. The female CPUE based on the WRC electrofishing survey will be used in conjunction with a second index for triggering management action.

Figure 11 shows the juvenile abundance index from the DMF juvenile seine survey. The juvenile abundance index did not exceed the threshold in 2024. Figure 12 shows the female CPUE based on the DMF Albemarle Sound IGNS. Figure 13 shows the CPUE based on the WRC electrofishing survey. Figure 14 shows the female relative F based on commercial landings and a hind cast three-year average of the DMF IGNS index.

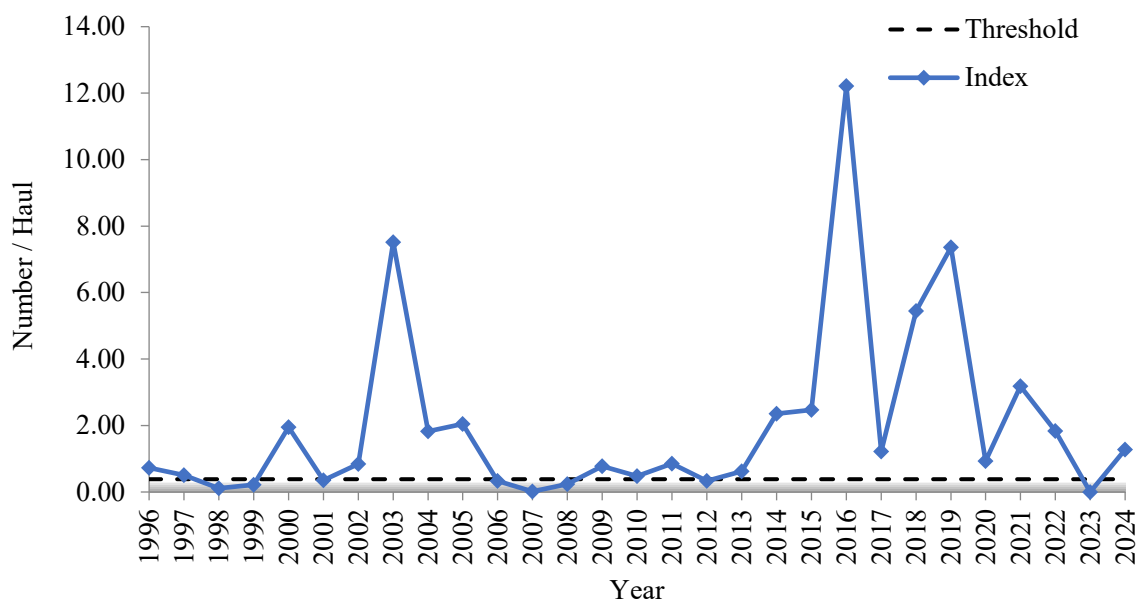

Figure 11 Juvenile abundance index from the DMF juvenile seine survey (Jun–Oct) for the Albemarle Sound, 1996–2024. Threshold represents 25th percentile (where 75% of all values are greater). Values in gray are below the threshold.

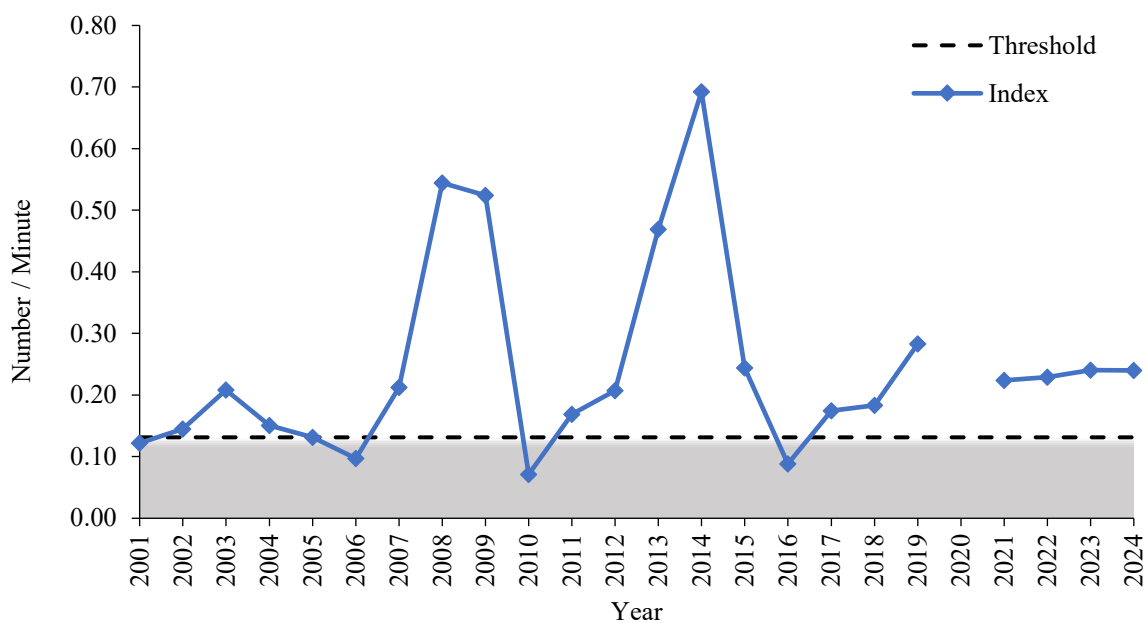

Figure 12. Female index from WRC electrofishing survey (March–May) for Roanoke River, 2001–2024. Threshold represents 25th percentile (where 75% of all values are greater). Values in gray are below the threshold. No survey data available for 2020.

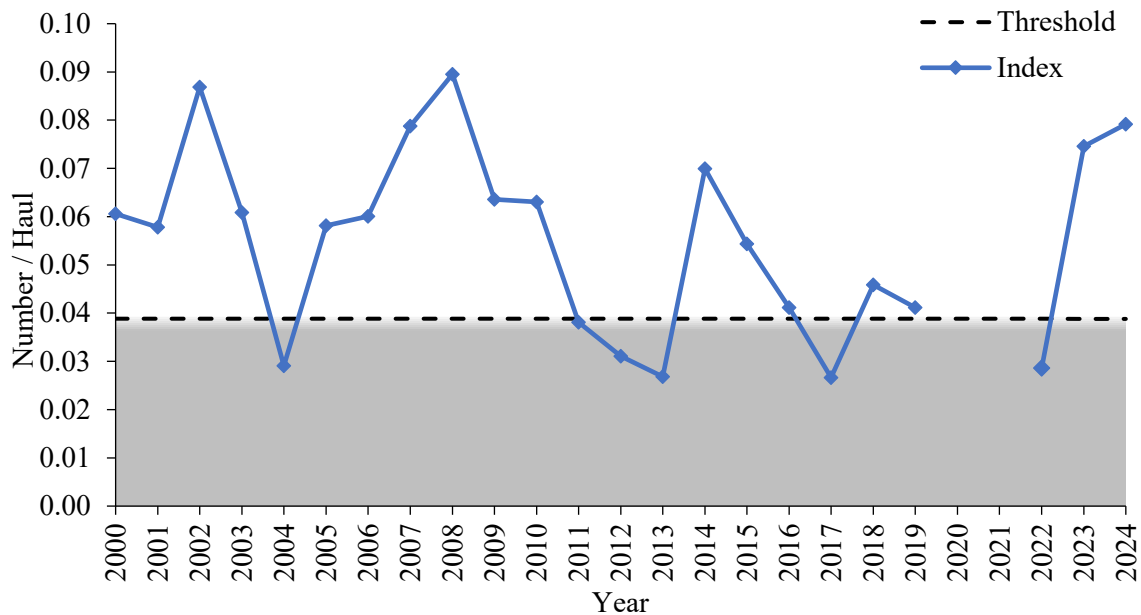

Figure 13. Female index from IGNS (January–May) for Albemarle Sound, 2000–2024. Threshold represents 25th percentile (where 75% of all values are greater. Values in gray are below the threshold. No survey data available for 2020–2021.

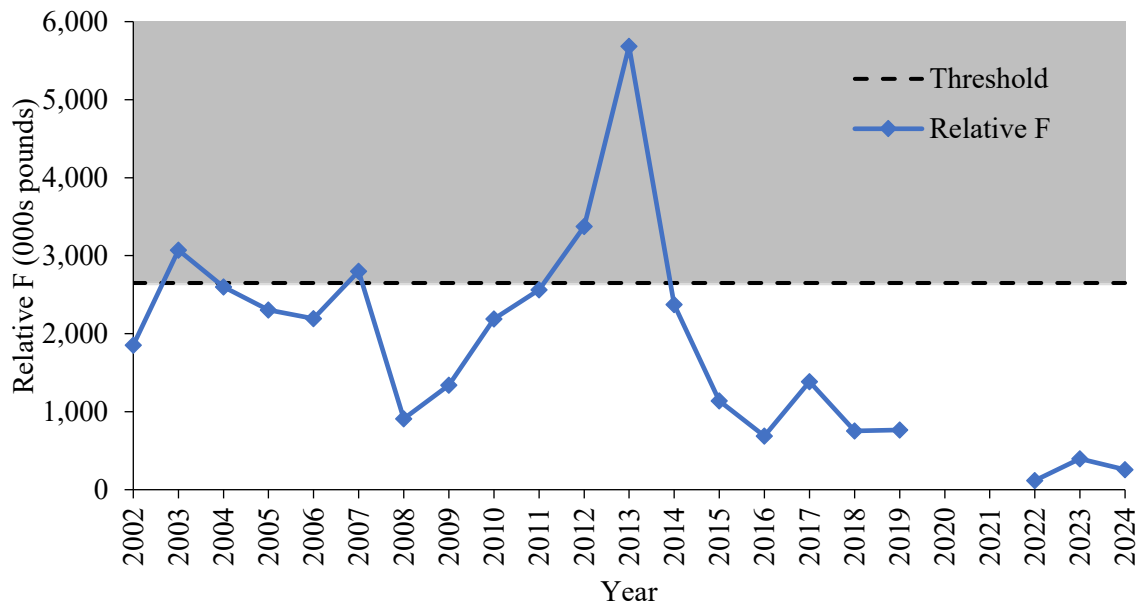

Figure 14. Albemarle Sound sustainability parameter for female relative F expressed in pounds of female fish, 2002–2024. The threshold represents the 75th percentile (where 25% of all values are greater), values in gray are exceeding the threshold. No survey data available for 2020 and 2021.

Tar-Pamlico River system

The Tar-Pamlico system has two sustainability parameters: female CPUE based on the WRC electrofishing survey, and female relative F based on the WRC electrofishing survey. Female relative F is calculated using

the combined commercial and recreational harvest from the Tar-Pamlico River and the female CPUE index from the Tar-Pamlico River electrofishing survey.

Figure 15 shows the female CPUE based on the WRC electrofishing survey and Figure 16 shows the female relative F based on the WRC electrofishing survey.

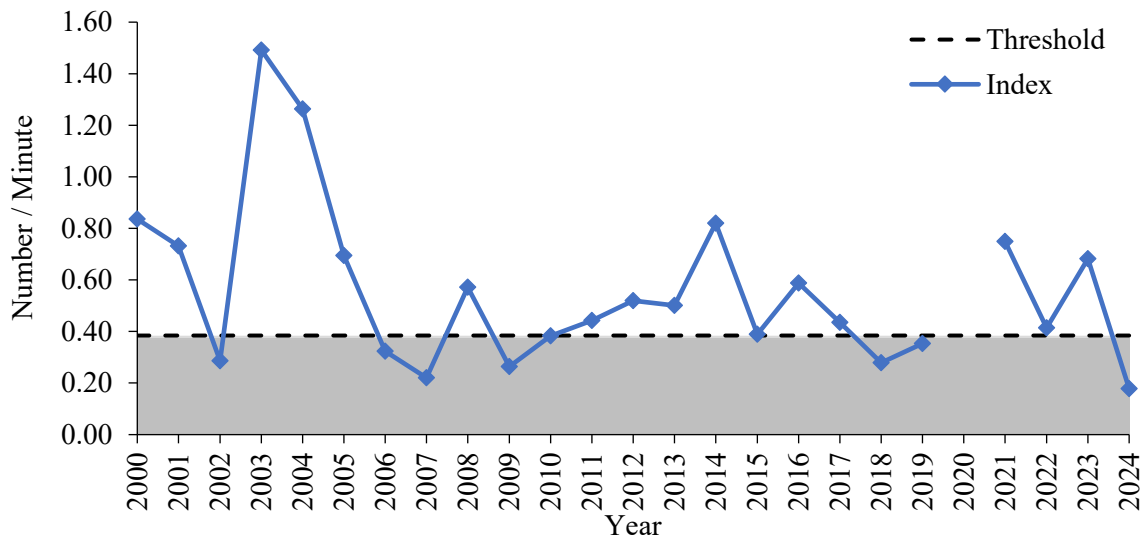

Figure 15. Female electrofishing index (March–May) for the Tar-Pamlico River, 2000–2024. The threshold represents the 25th percentile (where 75% of all values are greater). Values in gray are below the threshold. No survey data available for 2020.

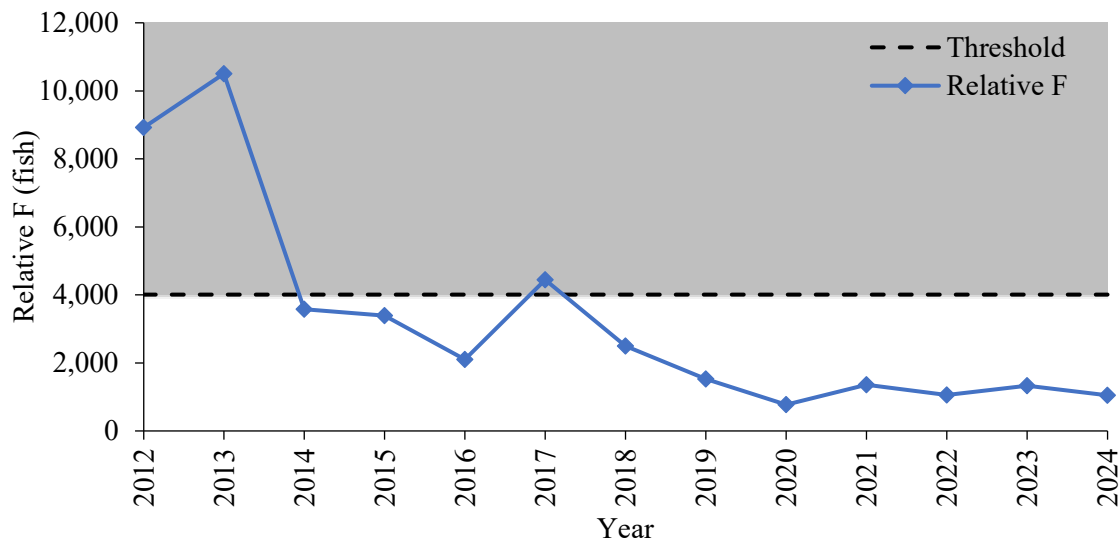

Figure 16. Tar-Pamlico River system sustainability parameter for female relative F in WRC electrofishing survey, 2012–2024. The threshold represents the 75th percentile (where 25% of all values are greater), values in gray are exceeding the threshold.

Neuse River system

The Neuse River system has two sustainability parameters: female CPUE based on the WRC electrofishing survey, and female relative F based on the WRC electrofishing survey. Female relative F is calculated using

the combined commercial and recreational harvest from the Neuse River and the female CPUE index from the Neuse River electrofishing survey.

Figure 17 shows the female CPUE based on the WRC electrofishing survey and Figure 18 shows the female relative F based on the WRC electrofishing survey.

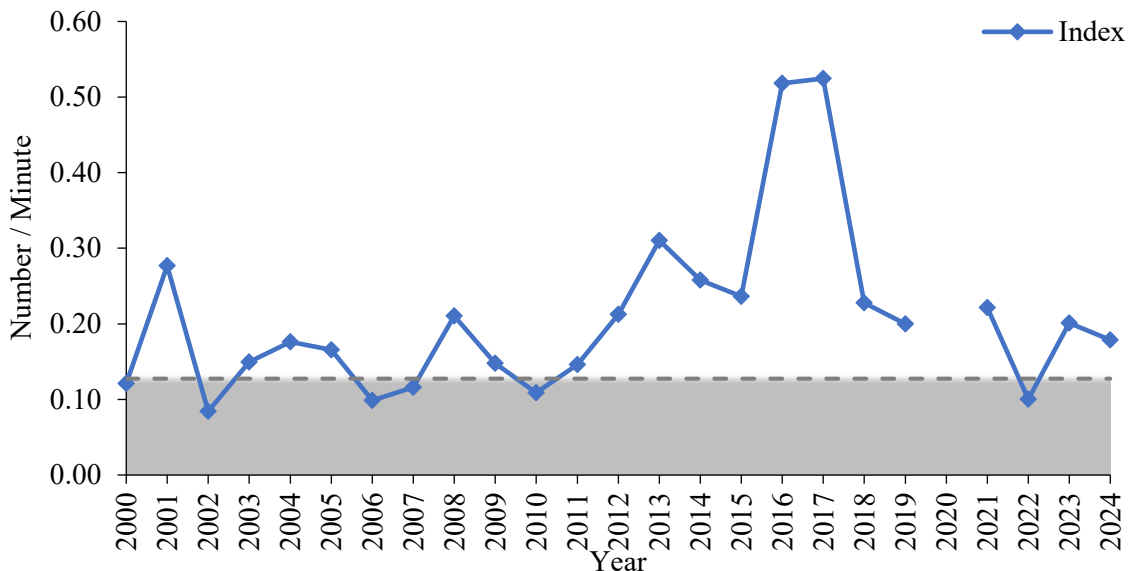

Figure 17. Female electrofishing index (March–May) for the Neuse River, 2000–2024. The threshold represents the 25th percentile (where 75% of all values are greater). Values in gray are below the threshold. No survey data available for 2020.

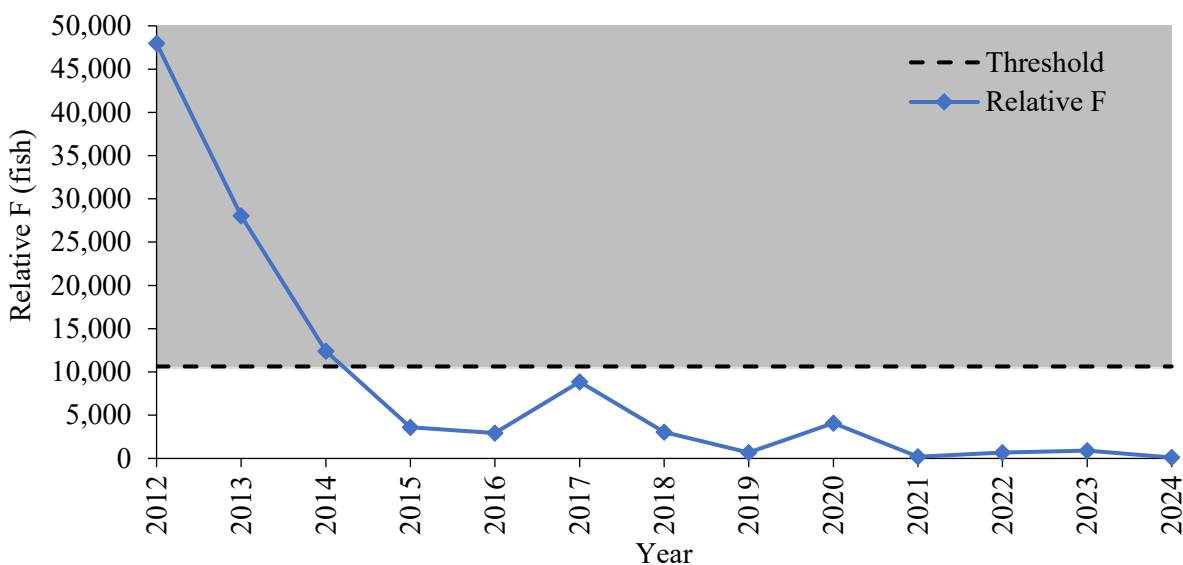

Figure 18. Neuse River system sustainability parameter for female relative F in WRC electrofishing survey, 2012–2024. The threshold represents the 75th percentile (where 25% of all values are greater), values in gray are exceeding the threshold.

Cape Fear River system

The Cape Fear River system has two sustainability parameters: female CPUE based on the WRC electrofishing survey, and female relative F based on the WRC electrofishing survey. Female relative F is calculated using the combined commercial and recreational harvest from the Cape Fear River and the female CPUE index from the Cape Fear River electrofishing survey.

Figure 19 shows the female CPUE based on the WRC electrofishing survey and Figure 20 shows the female relative F based on the WRC electrofishing survey.

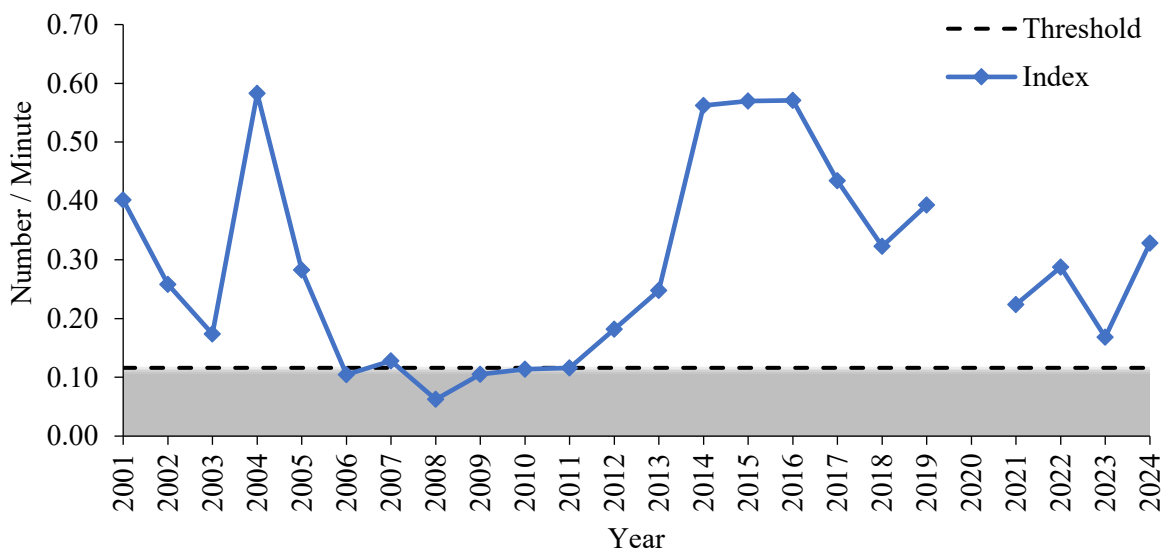

Figure 19. Female electrofishing index (March–May) for the Cape Fear River (LD-1 and LD-2, only), 2001–2024. The threshold represents the 25th percentile (where 75% of all values are greater). Values in gray are below the threshold. No survey data available for 2020.

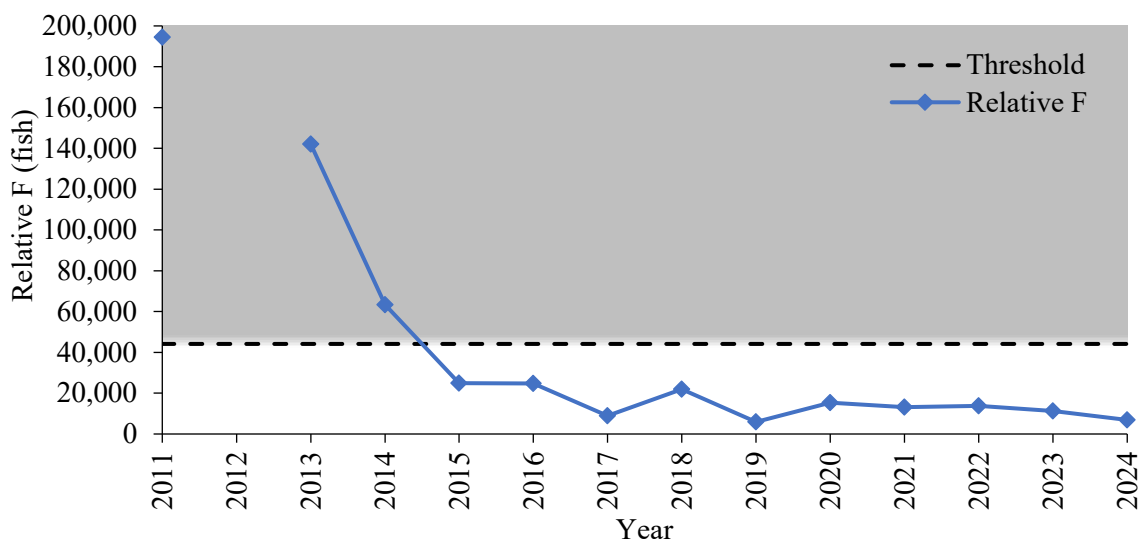

Figure 20. Cape Fear River system sustainability parameter for female relative F in WRC electrofishing survey, 2011–2024. The threshold represents the 75th percentile (where 25% of all values are greater), values in gray are exceeding the threshold.

All Other Internal Coastal and Joint Fishing Waters

The areas without specified sustainability parameters will fall under statewide management measures listed in the following section. The DMF monitors commercial landings through the North Carolina Trip Ticket Program to ensure landings remain low. Dedicated monitoring programs or area closures will be implemented if sudden increases in landings, indicating targeted effort, occur.

Management Measures for 2025

Recreational

Statewide Internal Waters including Albemarle Sound-Roanoke River, Neuse River, except as exempted below:

- It is unlawful to possess more than ten (10) American shad or hickory shad in the aggregate, per person per day taken by hook-and-line or for recreational purposes and only one (1) of the ten (10) may be an American shad.

Tar-Pamlico River, Pee Dee River

- It is unlawful to possess more than ten (10) American shad or hickory shad, in the aggregate, per person per day taken by hook-and-line or for recreational purposes.

Cape Fear River

- It is unlawful to possess more than ten (10) American shad or hickory shad in the aggregate, per person per day taken by hook-and-line or for recreational purposes and only five (5) of the ten (10) may be an American shad.

Commercial

Albemarle Sound Coastal and Joint Fishing Waters

- For 2025, a commercial season of February 15–April 14 has been established based on sustainability parameters for this system.
- The commercial season may occur anytime between January 1–April 14 for the 5-year tenure of this plan.

Tar-Pamlico River, Neuse River Coastal and Joint Fishing Waters

- For 2025, a commercial season of February 15–April 14 has been established based on sustainability parameters for this system.
- The commercial season may occur anytime between February 15–April 14 for the 5-year tenure of this plan.

Cape Fear River Coastal and Joint Fishing Waters

- For 2025, a commercial season of February 20–April 11 has been established based on sustainability parameters for this system.
- The commercial season may occur anytime between February 20–April 11 for the 5-year tenure of this plan.

All Other Internal Coastal and Joint Fishing Waters

- For 2025, a commercial season of February 15–April 14 has been established based on the Tar-Pamlico River, Neuse River, and Cape Fear River sustainability parameters.
- The commercial season may occur anytime between February 15–April 14 for the 5-year tenure of this plan.

While none of the selected sustainability parameters for any of the river systems have exceeded the triggers for management since 2013, the above measures for 2024 are considered prudent given the results of the 2020 stock assessment as they pertain to North Carolina. The Albemarle Sound is the only system in North Carolina where abundance status, relative to historic levels, was determined to be not depleted. The overall status for the other areas remains unknown, in large part due to a lack of juvenile data. The Albemarle Sound adult total mortality rate was determined sustainable, and abundance determined to be not overfished. Additionally, the Albemarle Sound juvenile abundance demonstrated an increasing trend during 2005–2017, the selected time period for abundance trends (ASMFC 2020). Given the Albemarle Sound status determination and the management measures in place for striped bass conservation also benefiting American shad (Section 4.2.1), the ASWG elected to expand the potential time frame in which the Albemarle Sound commercial fishery can occur from March 3–24 to January 1–April 14. The expanded time frame allows for flexibility in management to ensure that the fishery remains sustainable while maximizing the opportunity to stakeholders impacted by management restrictions for striped bass in this area. Commercial seasons, for all areas, will be determined after DMF and WRC jointly review the performance of the plan, annually, to determine management measures for the following season. Future changes to creel limits for American shad in the Inland Fishing Waters of the other river systems will also be complemented by DMF for Joint and Coastal Fishing Waters.
