APPENDIX C – PHOTO LOG

EXECUTIVE SUMMARY

The Brown Farm Wetland Restoration Project restored 24.6 acres and enhanced 3.3 acres of riparian wetland. New Hope Creek, which runs adjacent to the site, has a contributing drainage area of 33.3 square miles (21,331 acres) at the downstream limits of the site and is located within USGS 8-digit HUC 03030002 and NCDWQ Sub-basin 03-06-05 of the Cape Fear River Basin. The 46.1-acre project site is located on an active floodplain of New Hope Creek along the Orange-Durham County line. The restoration was completed to achieve the following objectives:

- Restore aquatic/terrestrial habitat
- Improve water quality
- Increase groundwater recharge
- Enhance nutrient cycling
- Restore a native bottomland hardwood community

Project construction occurred in November 2006. Construction involved plugging and filling ditches, installing level spreaders, and creating microtopography. The site was planted with native trees and shrubs common to Piedmont Bottomland Hardwood communities. Following construction and planting, baseline data collection occurred in February 2007. This report describes the fourth year of monitoring that took place in 2010.

Vegetation was planted at densities of approximately 436 and 100-200 stems per acre in the restored and enhanced wetlands, respectively. Twenty vegetation plots are monitored to assess planted vegetation survivability, growth, and vigor. The fourth year of monitoring counted an average of 310 planted stems/acre, which is slightly below the success criterion of 320 stems/acre. However, the site averages 1,020 total stems/acre, which includes woody volunteers in the monitoring plots excluding red maple (*Acer rubrum*) and sweetgum (*Liquidambar styraciflua*). Supplemental planting with bare root trees was conducted at the site in the winter of 2009/2010. The planting stock was selected to be larger than traditional bare root material. A few of the monitoring plots had planted trees in them. An assessment of the site's vegetation found Chinese privet (*Ligustrum sinense*), Japanese honeysuckle (*Lonicera japonica*), and multiflora rose (*Rosa multiflora*) on the outskirts of the site with Chinese lespedeza (*Lespedeza cuneata*) and thistle (*Cirsium* sp.) observed within the site. These species will continue to be monitored to determine if other corrective action is necessary. Fourth year monitoring found the vegetation component of the project to be on track to meeting the success criteria.

The hydrology success criterion states that groundwater must be within 12 inches of the soil surface in excess of 12 consecutive days (5% of the growing season) at each well. During 2010, wetland hydrology was achieved at all seven wells in the restoration area and the well in the reference wetland, with five of the seven wells having hydroperiods longer than 12.5% of the growing season.

The daily rainfall data depicted on the gauge data graphs were obtained from the on-site precipitation gauge. The precipitation gauge was installed in 2006 prior to project implementation. Daily rainfall data were obtained from the State Climate Office of North Carolina for Durham, North Carolina to confirm on-site precipitation data. The combined precipitation data show that the site experienced normal precipitation during the 2010 growing season.

Site photographs were taken from permanent photo points established throughout the site. Photo documentation facilitates the qualitative evaluation of wetland conditions. The photo point locations were selected in order to document representative site conditions.

The results of the fourth year of monitoring of the Brown Farm Wetland Restoration Project indicate that the site is on track to meeting the project's success criteria.

1.0 PROJECT BACKGROUND

1.1 Project Objectives

- Restore aquatic/terrestrial wildlife habitat
- Improve water quality
- Increase groundwater recharge
- Enhance nutrient cycling
- Restore a native bottomland hardwood community

1.2 Project Structure, Restoration Type, and Approach

Before restoration, the land use was primarily agricultural for at least the past 50 years. The wetland was restored by plugging and filling drainage ditches throughout the site, removing ditch spoil from wooded areas to restore natural drainage patterns, placing water diversion features to redistribute the surface hydrology, recreating microtopography across the site to enhance surface water retention and storage, and planting the site with Piedmont Bottomland Hardwood Forest species.

1.3 Location and Setting

The Brown Farm Wetland Restoration Site is located within the 03030002 (Upper Cape Fear 02) Watershed Cataloging Unit (8-digit HUC) and North Carolina Division of Water Quality (NCDWQ) Sub-basin 03-06-05 (Figure 1). New Hope Creek, which runs adjacent to the site, has a contributing drainage area of 33.3 square miles (21,331 acres) at the downstream limits of the project. Jordan Lake is approximately 11 miles downstream of the site. The project watershed is located within the Piedmont physiographic province and is part of the Triassic Basins Level IV Ecoregion.

2.0 PROJECT CONDITIONS AND MONITORING RESULTS

2.1 Vegetation Assessment

The site is immediately adjacent to well-developed wetlands within the New Hope Creek floodplain with extensive wetland vegetation. These surrounding areas have helped seed the site, contributing to a large number of volunteers in the monitoring plots. There was an increase in the site average of planted stems/acre during the fourth monitoring year. This reflects the addition of planted trees as well as trees that had been counted as dead resprouting. The mortality of the planted stems is primarily related to deer browse and competition from dense herbaceous vegetation. The volunteer plants that were counted during the 2010 monitoring include: green ash (*Fraxinus pennsylvanica*), buttonbush (*Cephalanthus occidentalis*), willow oak (*Quercus phellos*), sycamore (*Platanus occidentalis*), eastern baccharis (*Baccharis halimifolia*), and slippery elm (*Ulmus fulva*). Red maple (*Acer rubrum*) and sweetgum (*Liquidambar styraciflua*) were also counted, but since they are common successional species, they were not included in the density calculations for this report. The fourth year of monitoring found an average of 310 planted stems/acre and 1,052 total stems/acre for the site based on the monitored vegetation plots. Even though there has been some mortality of the planted stems, based on the average total stems/acre, the site is on track to meeting the success criteria set in the restoration plan of 320 stems/acre.

The qualitative vegetation assessment of the site found that there were many woody stems throughout the site and that there is a healthy mix of wetland herbaceous vegetation covering the site as well. For additional data on the counted stems, volunteer stems, and photos of the vegetation plots, see Appendix A.

The wetland wells used to monitor site hydrology were installed in early 2007. The maximum number of consecutive days that the groundwater was within 12 inches of the surface was determined for each groundwater gauge. This number was converted into a percentage of the 223-day growing season. Wetland hydrology was achieved at all of the gauges on the site in 2010 (Table 5). Based on these data, the site has exceeded the minimum duration of 12 consecutive days with the water table within 12 inches of the soil surface for the 2010 growing season (Appendix B). In addition, five of the gauges exceeded 12.5% saturation. Table 5 presents the hydrological monitoring results for 2010. Climatic data for the 2010 growing season were analyzed in comparison to historical data to determine whether 2010 was a normal year in terms of climatic conditions as a precursor to validating the results of the wetland monitoring. The historical data were collected from the NRCS, Water and Climate Center, “Climate Analysis for Wetlands by County” website. This evaluation concluded that 2010 was a normal year for rainfall during the growing season. Rainfall was within the 30th to 70th percentiles for the months of February, June, July, and August. Rainfall was less than the 30th percentile threshold in January, March, April, and October and was greater than the 70th percentile threshold in May and September (Appendix B).

To illustrate that the site is a riverine system, a stream gauge was installed on New Hope Creek to document overbank flooding. This gauge was installed in February 2008. Since installation, the gauge has recorded 40 overbank flooding events (over 253.8' elevation). These events typically flood approximately 75% of the site.
