EXECUTIVE SUMMARY

Restoration Systems has completed restoration of streams and wetlands at the Cane Creek Stream and Wetland Restoration Site to assist the North Carolina Ecosystem Enhancement Program (NCEEP) in fulfilling stream and wetland mitigation goals. The Site is located in north Rutherford County less than 0.2 mile south of the Rutherford/McDowell County line along the eastern edge of Highway 64. The Site is located in United States Geological Survey Hydrologic Unit 03050105060020 (North Carolina Division of Water Quality Subbasin 03-08-02) of the Broad River Basin and will service the USGS 8-digit Cataloging Unit (CU) 03050105. The Site is not located in a Targeted Local Watershed. This report serves as the Year 1 (2008) annual monitoring report.

Primary activities at the Site included 1) stream restoration, 2) stream enhancement, 3) stream preservation, 4) wetland restoration, 5) soil scarification, and 6) plant community restoration. Project restoration efforts provide a minimum of 6748 Stream Mitigation Units, 4.4 riverine Wetland Mitigation Units, and 5.0 nonriverine Wetland Mitigation Units as outlined in the March 2006 Technical Proposal.

Fifteen vegetation plots (10 meters by 10 meters in size) were established and permanently monumented. These plots were surveyed in September 2008 for the Year 1 (2008) monitoring season. Vegetation sampling across the Site was below the required average density with 213 planted stems per acre surviving; eleven of the fifteen plots had low densities for the Year 1 (2008) monitoring season. Rutherford County has been in an extreme drought for the entire growing season, which negatively affected the viability of planted stems. For the months of April to October the Site experienced only about 21 inches of rain, based on onsite rain gauge data and data collected at a nearby rain station, compared to the 30-year historic mean of 28 inches for the area. The southwestern region of North Carolina in which the Cane Creek Site is located has been under drought conditions ranging from Extreme (D-3) to Exceptional (D4) for more than a year. Restoration Systems has scheduled to have the entire Site replanted in early 2009 at a rate of 680 stems per acre to rectify the problem. In addition, kudzu has begun encroaching into the northern portion of the Site; however, active measures including spraying and manual removal to control this invasive species have been initiated and will continue as necessary.

Twenty cross-sections and longitudinal profiles within five 600-foot reaches were measured for the Year 1 (2008) monitoring. As a whole, monitoring measurements indicate that there have been minimal changes in both the longitudinal profile and cross-sections as compared to as-built data. The as-built channel geometry compares favorably with the emulated, stable E/C type stream reach as set forth in the detailed mitigation plan and construction plans. Current monitoring has demonstrated dimension, pattern, and profile were stable over the course of the monitoring period. No stream problem areas were noted within the Site during the Year 1 (2008) monitoring year.

None of the five monitored gauges within restoration areas were inundated/saturated within 12 inches of the surface for greater than 5 percent of the growing season, which extends from April 4 to November 6 (217 days). Rainfall for the Year 1 (2008) growing season was below normal; therefore, comparisons to the reference groundwater gauge were made. One of the five groundwater gauges should be considered successful for the Year 1 (2008) monitoring period.

1.0 PROJECT BACKGROUND

1.1 Location and Setting

Restoration Systems, L.L.C. (Restoration Systems) has completed restoration of streams and wetlands at the Cane Creek Stream and Wetland Restoration Site (hereafter referred to as the “Site”) to assist the North Carolina Ecosystem Enhancement Program (EEP) in fulfilling stream and wetland mitigation goals. The Site is located in north Rutherford County less than 0.2 mile south of the Rutherford/McDowell County line along the eastern edge of Highway 64. The Site is located in United States Geological Survey (USGS) Hydrologic Unit (HU) 03050105060020 (North Carolina Division of Water Quality [NCDWQ] Subbasin 03-08-02) of the Broad River Basin and will service the USGS 8-digit Cataloging Unit (CU) 03050105. The Site is not located in a Targeted Local Watershed.

Directions to the Site from Rutherfordton, North Carolina, are as follows:

- Travel northeast on Highway 64 for approximately 15 miles
- The Site is on the right ~0.2 miles south of the Rutherford and McDowell County lines.

1.2 Project Objectives

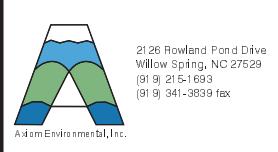

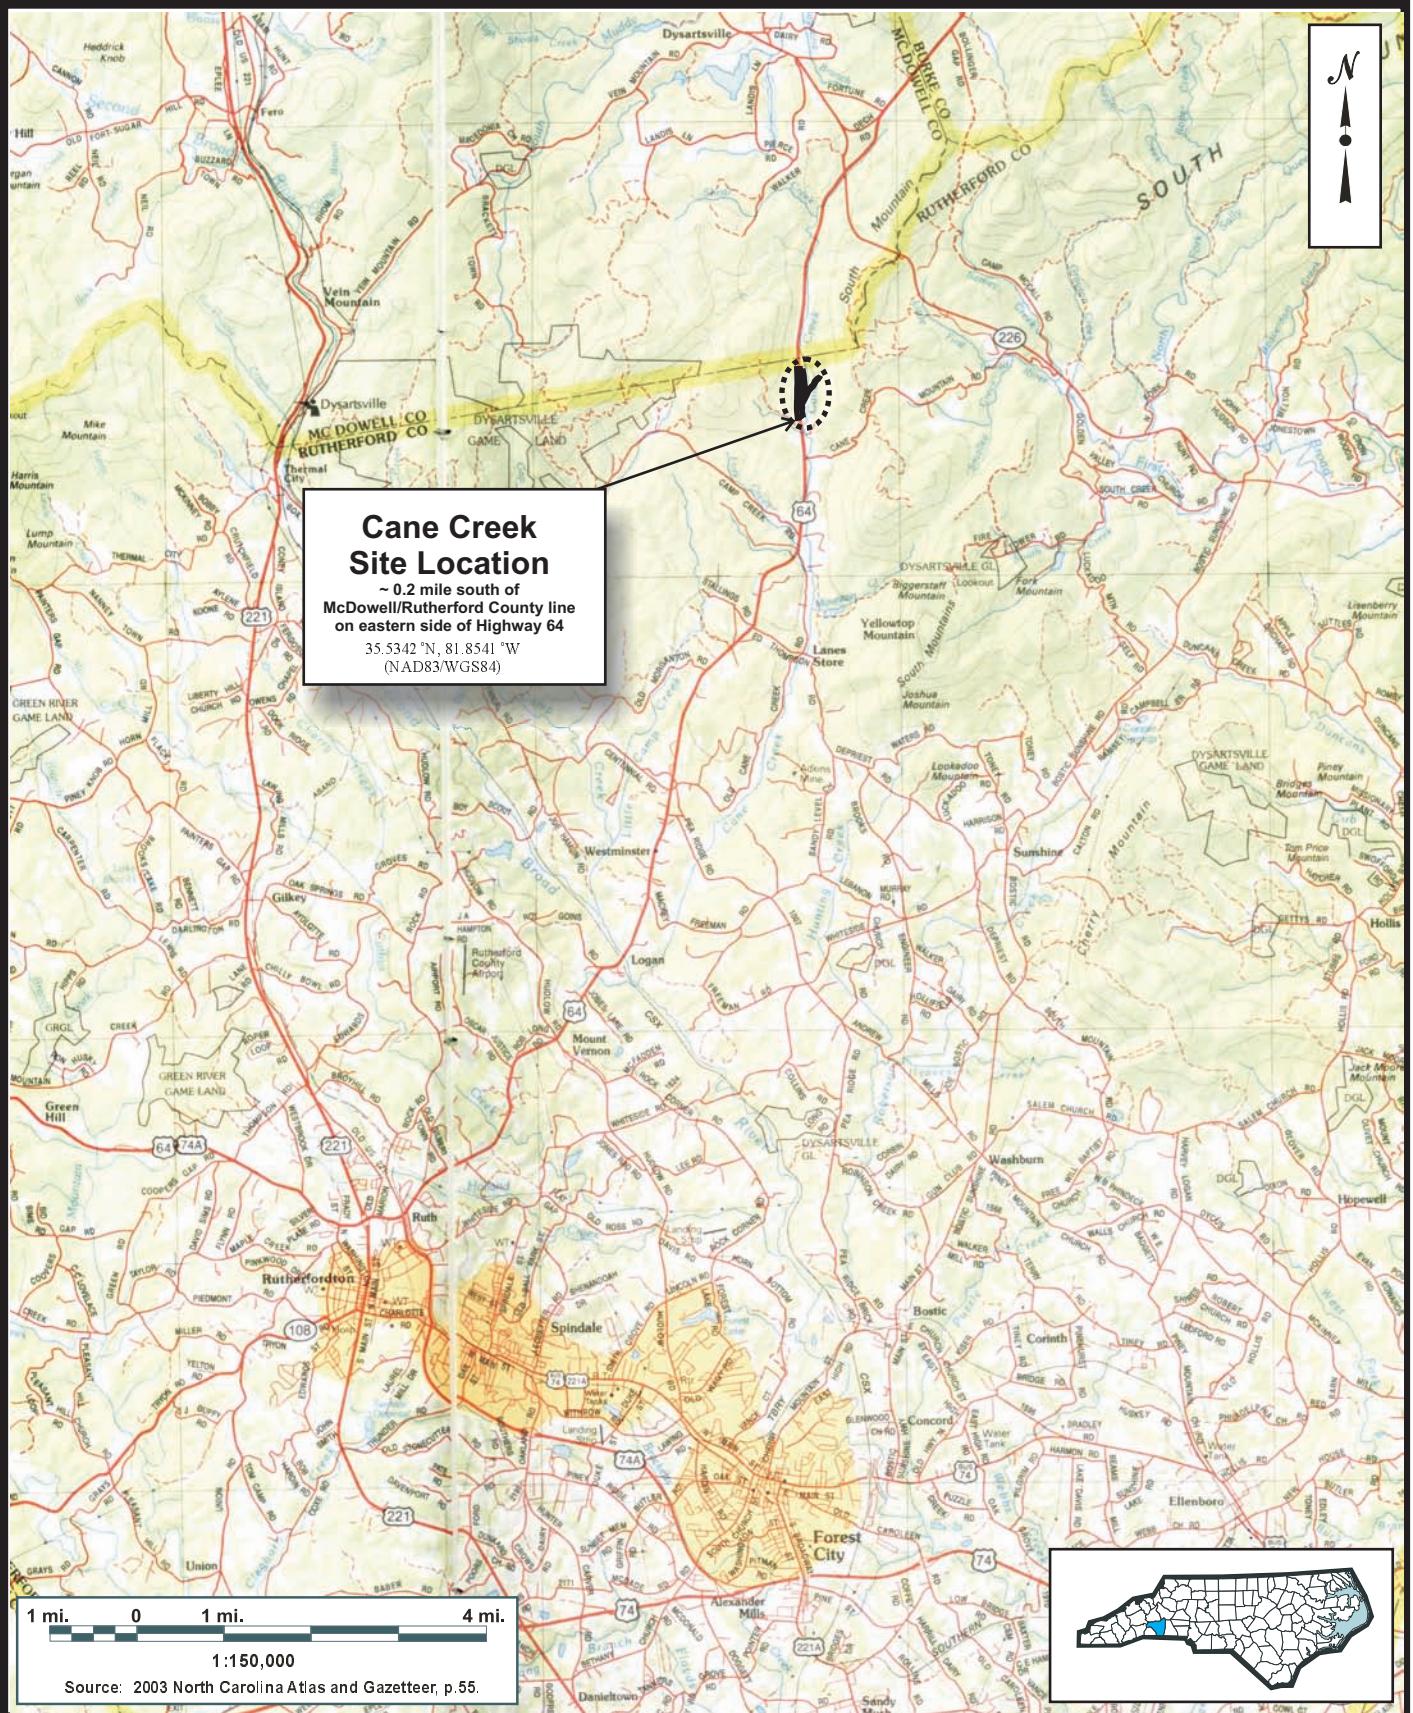

The primary components of the restoration project included 1) construction of a stable, riffle-pool stream channel; 2) enhancement of water quality functions within, upstream, and downstream of the Site; 3) creation of a natural vegetated buffer along restored stream channels; 4) restoration of jurisdictional riverine and nonriverine wetlands in the Site; 5) improvement of aquatic habitat and species diversity by enhancing stream bed variability; and 6) restoration of wildlife functions associated with a riparian corridor/stable stream.

1.3 Project Structure, Restoration Type, and Approach

An approximately 43.5-acre conservation easement was placed on the Site to incorporate all restoration activities. The Site contains 9.4 acres of hydric soil, Cane Creek, three unnamed tributaries to Cane Creek, and adjacent floodplains. An undisturbed preservation reach located on the upper extents of Tributary 1 within the Site was utilized as the reference reach. Prior to implementation, the Site was characterized by agricultural land utilized primarily for row crop and hay production. Riparian vegetation adjacent to Site streams was sparse and disturbed due to plowing and regular maintenance, and row crop areas were subject to broadcast application of various agricultural chemicals.

Restoration, enhancement, and preservation of Site streams and wetlands will result in positive benefits for water quality and biological diversity in the Cane Creek watershed. Targeted mitigation efforts focused on improving water quality, enhancing flood attenuation, and restoring aquatic and riparian habitat and were accomplished by:

1. Removing nonpoint and point sources of pollution associated with agricultural practices including a) cessation of broadcasting fertilizer, pesticides, and other agricultural chemicals into and adjacent to the Site and b) provide a forested riparian buffer to treat surface runoff.
2. Reducing sedimentation within onsite and downstream receiving waters by a) reducing bank erosion associated with vegetation maintenance and agricultural plowing up to Site streams, and b) planting a forested riparian buffer adjacent to Site streams.
3. Reestablishing stream stability and the capacity to transport watershed flows and sediment loads by restoring a stable dimension, pattern, and profile supported by natural in-stream habitat and grade/bank stabilization structures.

4. Promoting floodwater attenuation by a) reconnecting bankfull stream flows to the abandoned floodplain terrace; b) restoring secondary, dredged, straightened, and entrenched tributaries, thereby reducing floodwater velocities within smaller catchment basins; and c) revegetating Site floodplains to increase frictional resistance on floodwaters.
5. Restoring onsite wetlands, thereby promoting flood storage, nutrient cycling, and aquatic wildlife habitat.
6. Improving aquatic habitat with bed variability and the use of in-stream structures.
7. Providing a terrestrial wildlife corridor and refuge in an area that is developed for agricultural and timber production.
8. Providing connectivity to a State Nature Preserve northeast of the Site.

Table 1 describes the Site restoration structures and objectives, which have provided a minimum of 6748 Stream Mitigation Units, 4.4 riverine Wetland Mitigation Units, and 5.0 nonriverine Wetland Mitigation Units as outlined in the March 2006 Technical Proposal as follows.

- Restoration of 4600 linear feet of stream within three UTs to Cane Creek by constructing meandering channels.
- Enhancement of (level II) 5708 linear feet of Cane Creek.
- Preservation of 1506 linear feet of the upper reaches of an unnamed tributary to Cane Creek.
- Restore 4.4 acres of jurisdictional riverine wetland by reestablishing historic water table elevations.
- Restore 5.0 acres of jurisdictional nonriverine wetland by filling ditches.
- Reforest approximately 30 acres of the Site with native forest species.

1.5 Monitoring Plan View

Monitoring activities for the Site, including relevant structures and utilities, project features, specific project structures, and monitoring features are detailed in the monitoring plan view in Appendix D. Site features including vegetation, stream dimension (cross-sections), stream profile and pattern, wetland hydrology, and photographic documentation were monitored in Year 1 (2008).

2.0 PROJECT CONDITION AND MONITORING RESULTS

2.1 Vegetation Assessment

Following Site construction, fifteen plots (10 meters by 10 meters in size) were established and monumented with metal fence posts at all plot corners and PVC at each plot origin. Sampling was conducted as outlined in the *CVS-EEP Protocol for Recording Vegetation, Version 4.0* (Lee et al. 2006) (<http://cvs.bio.unc.edu/methods.htm>); results are included in Appendix A. The taxonomic standard for vegetation used for this document was *Flora of the Carolinas, Virginia, Georgia, and Surrounding Areas* (Weakley 2007). The locations of vegetation monitoring plots were placed to accurately represent the entire Site and are depicted on the monitoring plan view in Appendix D.

2.1.1 Vegetation Success Criteria

Success criteria have been established to verify that the vegetation component supports community elements necessary for forest development. Success criteria are dependent upon the density and growth of characteristic forest species. Additional success criteria are dependent upon density and growth of "Characteristic Tree Species." Characteristic Tree Species include planted species, species identified through inventory of a reference (relatively undisturbed) forest community used to orient the planting plan, and appropriate Schafale and Weakley (1990) community descriptions. All canopy tree species planted and identified in the reference forest will be utilized to define "Characteristic Tree Species" as termed in the success criteria. Table 5 below outlines planted and reference forest species.

Table 5. Planted Species and Reference Forest Ecosystem

Planted Species	Reference Species
Pawpaw (<i>Asimina triloba</i>)	Red maple (<i>Acer rubrum</i>)
Mockernut hickory (<i>Carya alba/tomentosa</i>)	Ironwood (<i>Carpinus caroliniana</i>)
Hackberry (<i>Celtis laevigata</i>)	Mockernut hickory (<i>Carya alba</i>)
Buttonbush(<i>Cephalanthus occidentalis</i>)	Hickory (<i>Carya</i> sp.)
Silky dogwood(<i>Cornus amomum</i>)	Dogwood (<i>Cornus florida</i>)
Persimmon (<i>Diospyros virginiana</i>)	Persimmon (<i>Diospyros virginiana</i>)
Green ash (<i>Fraxinus pennsylvanica</i>)	American beech (<i>Fagus grandifolia</i>)
Sycamore (<i>Platanus occidentalis</i>)	Eastern red cedar (<i>Juniperus virginiana</i>)
Black cherry (<i>Prunus serotina</i>)	Mountain laurel (<i>Kalmia latifolia</i>)
White oak (<i>Quercus alba</i>)	Doghobble (<i>Leucothoe fontanesiana</i>)
Swamp chestnut oak (<i>Quercus michauxii</i>)	Sycamore (<i>Platanus occidentalis</i>)
Cherrybark oak (<i>Quercus pagoda</i>)	Black cherry (<i>Prunus serotina</i>)
Northern red oak (<i>Quercus rubra</i>)	White oak (<i>Quercus alba</i>)
Elderberry(<i>Sambucus canadensis</i>)	Northern red oak (<i>Quercus rubra</i>)
American elm (<i>Ulmus americana</i>)	

Success criteria dictate that an average density of 320 stems per acre of Character Tree Species must be surviving in the first three monitoring years. Subsequently, 290 Character Tree Species per acre must be surviving in Year 4 and 260 Character Tree Species per acre in Year 5.

2.1.2 Vegetative Problem Areas

Vegetation sampling across the Site was below the required average density with 213 planted stems per acre surviving; eleven of the fifteen plots had low densities for the Year 1 (2008) monitoring season. Rutherford County has been in an extreme drought for the entire growing season negatively affecting the viability of planted stems (NCDWR 2008). For the months of April to October the Site experienced approximately 21 inches of rain, based on onsite rain gauge data and data collected at a nearby rain station, compared to the 30-year historic mean of 28 inches for the area (Weather Underground 2008, NOAA 2004). The region where the Site is located has experienced drought conditions ranging from Extreme (D-3) to Exceptional (D-4) from August, 2007 through the present (<http://www.drought.unl.edu/dm/monitor.html>). Restoration Systems has scheduled to replanted in early 2009 at a rate of 680 stems per acre to rectify the problem.

In addition, kudzu (*Pueraria montana*) has begun encroaching from an adjacent field into the northern portion of the Site and several stems of multiflora rose (*Rosa multiflora*) and privet (*Ligustrum sinense*) were observed at the southern end. All three invasive species were treated with the herbicide Milestone VM (aminopyralid) at a rate of seven ounces per acre. The treated areas will be monitored and treatments continued as necessary.

2.2 Stream Assessment

Twenty permanent cross-sections within five 600-foot reaches were established after construction was completed. Measurements of each cross-section include points at all breaks in slope including top of bank, bankfull, and thalweg. Riffle cross-sections are classified using the Rosgen stream classification system. Longitudinal profile measurements of five 600-foot reaches include thalweg, water surface, and bankfull; with each measurement taken at the head of facets (i.e. riffle, run, pool, and glide) in addition to the maximum pool depth.

2.2.1 Stream Success Criteria

Success criteria for stream restoration will include 1) successful classification of the reach as a functioning stream system (Rosgen 1996) and 2) channel variables indicative of a stable stream system. Annual monitoring will continue until success criteria are met and no less than two bankfull events have occurred, as determined by in situ crest gauge, otherwise monitoring will continue until the second bankfull event has occurred.

Visual assessment of in-stream structures will be conducted to determine if failure has occurred. Failure of a structure may be indicated by collapse of the structure, undermining of the structure, abandonment of the channel around the structure, and/or stream flow beneath the structure.

2.2.2 Bankfull Events

No bankfull events were documented during the Year 1 (2008) monitoring period.

Table 6. Verification of Bankfull Events

Date of Data Collection	Date of Occurrence	Method	Photo (if available)
No bankfull events were documented during the Year 1 (2008) monitoring period.			

2.2.3 Stream Problem Areas

No stream problem areas were noted within the Site during the Year 1 (2008) monitoring year.

2.2.4 Categorical Stream Feature Visual Stability Assessment

Each stream reach was visually inspected during the Year 1 (2008) monitoring period using eight feature categories and various metrics within each category. Assessment features included riffles, pools, thalweg, meanders, channel bed, structures, and root wads/boulders. Tables for semi-quantitative assessments of each reach are included in Appendix B (Tables B1-B5). The mean percentage of performance for features within each reach are summarized in the tables below.

Structures within Reaches 1 and 2 appear to have sunk slightly lowering the structure elevation within the channel; however, no instability has occurred upstream or downstream of the structures. In addition, one structure within Reach 3 has a minor amount of observed scour/piping; however, the scour/piping is minimal and is not causing any channel instability. Structures will continued to be monitored; however, no proactive measures are recommended at this time. The issues are minimal and are not causing any stream problems at this time.

2.2.5 Quantitative Stream Measurements

During the Year 1 (2008) monitoring period 20 cross-sections and longitudinal profiles within five 600-foot reaches were measured. Permanent cross-sections and longitudinal profiles are included in Appendix B; each is graphically depicted for as-built through Year 1 (2008) for analysis. As a whole, monitoring measurements indicate minimal changes in both the longitudinal profile and cross-sections as compared to as-built data. The channel geometry compares favorably with the emulated, stable E/C type stream reach as set forth in the detailed mitigation plan and as constructed. Current monitoring has demonstrated dimension, pattern, and profile were stable over the course of the monitoring period. Tables for quantitative assessments are included below; these tables include data from previous years. In addition, visual assessments of the enhancement of Cane Creek were completed; photographs are included in Appendix B.

2.3 Wetland Assessment

Five groundwater monitoring gauges and one reference groundwater gauge were maintained and monitored throughout the Year 1 (2008) growing season. Graphs of groundwater hydrology and precipitation from a nearby rain station for April to June (Weather Underground 2008) and an onsite rain gauge for the remainder of the growing season are included in Appendix C.

Table 9E. Morphology and Hydraulic Monitoring Summary

2.3.1 Wetland Success Criteria

Target hydrological characteristics include saturation or inundation for 5 to 12.5 percent of the growing season, during average climatic conditions. During growing seasons with atypical climatic conditions, groundwater gauges in reference wetlands may dictate threshold hydrology success criteria (75 percent of reference). These areas are expected to support hydrophytic vegetation. If wetland parameters are marginal as indicated by vegetation and/or hydrology monitoring, a jurisdictional determination will be performed.

2.3.2 Wetland Problem Areas

No wetland problem areas were identified within the Site during Year 1 (2008) monitoring.

2.3.3 Wetland Criteria Attainment

None of the five monitored gauges within restoration areas were inundated/saturated within 12 inches of the surface for greater than 5 percent of the growing season, which extends from April 4 to November 6 (217 days) (Table 10). However, rain fall for the Year 1 (2008) growing season was below normal with 21 inches of rain occurring from April to October 2008 compared to the 30-year historic mean rainfall of 28 inches occurring from March to October (Weather Underground 2008, NOAA 2004) (Figure 2). Since the Year 1 (2008) monitoring season rainfall was below normal, comparisons to the reference groundwater gauge was made. One of the five groundwater gauges should be considered successful for the Year 1 (2008) monitoring period. Hydrographs containing groundwater and precipitation data for each gauge can be found in Appendix B.

3.0 CONCLUSIONS

None of the five monitored gauges within restoration areas were inundated/saturated within 12 inches of the surface for greater than 5 percent of the growing season. However, rainfall for the Year 1 (2008) growing season was below normal with 21 inches of rain occurring from April to October 2008 compared to the 30-year historic mean rainfall of 28 inches occurring from March to October. Since the Year 1 (2008) monitoring season rainfall was below normal, comparisons to the reference groundwater gauge was made. One of the five groundwater gauges should be considered successful for the Year 1 (2008) monitoring period. A summary of groundwater gauge data for the Year 1 (2008) is included in Table 11.

Table 11. Summary of Groundwater Gauge Results

Gauge	Success Criteria Achieved/Max Consecutive Days During Growing Season (Percentage)				
	Year 1 (2008)	Year 2 (2009)	Year 3 (2010)	Year 4 (2011)	Year 5 (2012)
1	No/0 days (0 percent)				
2	No/0 days (0 percent)				
3	No/0 days (0 percent)				
4	No/1 days (0.5 percent)				
5	Yes/4 days (1.8 percent)				
Ref 1	Yes/2 days (0.9 percent)				

Vegetation sampling across the Site was below the required average density with 213 planted stems per acre surviving; eleven of the fifteen plots had low densities for the Year 1 (2008) monitoring season (Table 12). Rutherford County has been in an extreme drought for the entire growing season negatively affecting the viability of planted stems. Restoration Systems has scheduled to replanted in late 2008 or early 2009 at a rate of 680 stems per acre to rectify the problem.

- 2. Vegetation Monitoring Plot Photos**

Report Prepared By	Corri Faquin
Date Prepared	10/22/2008 9:58
database name	RestorationSystems-2008-Al-v2.2.5.mdb
database location	C:\Business\CVS database
computer name	AXIOM-0A9116A70

DESCRIPTION OF WORKSHEETS IN THIS DOCUMENT-----

Metadata	Description of database file, the report worksheets, and a summary of project(s) and project data.
Proj, planted	Each project is listed with its PLANTED stems per acre, for each year. This excludes live stakes.
Proj, total stems	Each project is listed with its TOTAL stems per acre, for each year. This includes live stakes, all planted stems, and all natural/volunteer stems.
Plots	List of plots surveyed with location and summary data (live stems, dead stems, missing, etc.).
Vigor	Frequency distribution of vigor classes for stems for all plots.
Vigor by Spp	Frequency distribution of vigor classes listed by species.
Damage	List of most frequent damage classes with number of occurrences and percent of total stems impacted by each.
Damage by Spp	Damage values tallied by type for each species.
Damage by Plot	Damage values tallied by type for each plot.
ALL Stems by Plot and spp	A matrix of the count of total living stems of each species (planted and natural volunteers combined) for each plot; dead and missing stems are excluded.

PROJECT SUMMARY-----
