1.0 EXECUTIVE SUMMARY

This Annual Report details the monitoring activities during the 2010 growing season (Monitoring Year 4) on the Crowns West Stream Restoration Site ("Site"). As per the approved Restoration Plan for the Site, this Annual Monitoring Report presents data on stream geometry, stem count data from vegetation monitoring stations, and discusses any observed tendencies relating to stream stability and vegetation survival success.

Crowns West Branch had been channelized and riparian vegetation had been cleared in the lower half of the Site. The upstream area had a degraded, early successional buffer that included several exotic species. Prior to restoration, Crowns West Branch was incised along its length and lacked bedform diversity. As a result, channel degradation was widespread throughout the Site. After construction, it was determined that 3,835 linear feet (LF) of stream were restored.

A total of 11 monitoring plots 100 square meters (m^2) (10m x 10m) in size were used to predict survivability of the woody vegetation planted on-site. Data from the Year 4 monitoring event of the 11 vegetation plots showed a range of 486 to 972 stems per acre, with an average survivability of 659 stems per acre. The site is currently on track for meeting the final success criteria of 260 trees per acre by the end of Year 5.

During Year 4 monitoring, kudzu (*Pueraria spp.*) and privet (*Ligustrum L.)* were observed on the Site. The kudzu is located east of Haw Branch Road and is present in the NC Division of Highways (NCDOT) right-of-way and also occurs within the project easement. The privet is located along the southern easement boundary, west of Haw Branch Road or along the right side of the restored channel west, of Haw Branch Road. The kudzu areas were treated in 2010 and are scheduled to be treated again during the 2011 growing season. The areas of privet were not treated during Year 4, but were previously treated in 2009. The privet is also scheduled to be treated during the 2011 growing season.

The total length of stream channel restored on the Site was 3,835 LF. This entire length was inspected during Year 4 of the monitoring period (2010) to assess stream performance. The visual stability assessment noted during Year 3 monitoring, several locations on M2 and the lower portion of M1 exhibited localized bank erosion, mostly in locations where sandy soils were present. During Year 4 of monitoring, these areas did not exhibit any further problems and do not call for repair at this time. According to the cross-section survey, stream dimension also remained stable during Year 4. The longitudinal profile for Year 4 showed that the in-stream structures and features are remaining stable.

The on-site crest gauge documented the occurrence of at least two bankfull flow events during Year 4 of the post-construction monitoring period. Inspection of conditions during site visits revealed visual evidence of out-of-bank flows. The largest on-site stream flow documented by the crest gauge during Year 4 of monitoring was approximately 3.72 feet (44.64 inches) above the bankfull stage.

Year 3 macro invertebrate sampling for Site 1 showed substantial improvements in the samples. The Year 3 post-restoration data has shown that the Site has developed from a newly established coastal plain stream system with a weak benthic macroinvertebrate community into a system that exhibits diverse habitat, is continuing to mature, and is able to support and cultivate biological diversity.

The Restoration Plan for the Site did not include wetland areas. Therefore, no groundwater monitoring stations or rain gauges were installed on the Site.

In summary, the Site is on track to meet the vegetative, hydrologic, and stream success criteria specified in the Site's Restoration Plan.

2.0 PROJECT BACKGROUND

The project involved the proposed restoration of 3,835 LF of stream. Table 1 summarizes the restoration areas on the Site. Selected site photographs are shown in Appendix A and B. A total of 10.8 acres of stream and riparian buffer are protected through a permanent conservation easement.

2.1 Project Objectives

The specific goals for the Crowns West Site Restoration Project were as follows:

- Restore 3,904 LF of channel dimension, pattern and profile
- Improve floodplain function by matching floodplain elevation with bankfull stage
- Establish native stream bank and floodplain vegetation in the 10.8-acre permanent conservation easement
- Improve water quality in the Crowns West and New River watersheds by reducing sediment and nutrient inputs
- Improve aquatic and riparian habitat by creating deeper pools and areas of re-aeration, planting a riparian buffer, and reducing bank erosion.

2.2 Project Structure, Restoration Type and Approach

For analysis and design purposes, Baker Engineering divided on-site streams into reaches. The reaches were numbered sequentially from west to east, with an "M" designation for "mainstem." M1 begins on the upstream portion of the project, and flows east, ending at Haw Branch Road. M2 begins at Haw Branch Road and flows east, to the end of the wood line at the downstream end of the project. One unnamed tributary (UT1) flowing from Haw Branch Road to the confluence with Crowns West Branch was originally proposed for restoration and was included in the 3,904 LF of stream restoration originally proposed for the Site. The landowner withdrew this short section of UT1 in exchange for additional property and stream length at the upstream section of M1 on Crowns West Branch. UT1 was to be tied into M2, as an alternative the tie-in point to M2 was stabilized.

The restoration design allows stream flows larger than bankfull flows to spread onto the floodplain, dissipating flow energies and reducing stress on streambanks. In-stream structures were used to control streambed grade, reduce streambank stress, and promote bedform sequences and habitat diversity. The in-stream structures consisted of root wads, log vanes, log weirs, and constructed riffles, which promote a diversity of habitat features in the restored channel. Where grade control was a consideration, constructed riffles were installed to provide long-term stability. Streambanks were stabilized using a combination of erosion control matting, temporary and permanent seeding, bare-root planting, and transplants. Transplants provide living root mass to increase streambank stability and create holding areas for fish and aquatic biota. Native vegetation was planted across the Site. The entire restoration project is protected through a permanent conservation easement.

*R = Restoration

**P1 = Priority I
P2 = Priority II

2.3 Location and Setting

The Site is located in Onslow County, NC (Figure 1), approximately six miles northwest of the town of Richlands. The Site lies in the White Oak River Basin within North Carolina Division of Water Quality sub-basin 03-05-02 and NCEEP targeted local watershed 03030001010010.

2.4 Project History and Background

Land use on the Site consisted primarily of row crop agriculture with adjacent woodlands. Crowns West Branch had been channelized and riparian vegetation had been cleared in the lower half of the Site. The upstream area had a degraded, early successional buffer that included several exotic species. Prior to restoration, Crowns West Branch was incised and lacked bedform diversity. As a result, channel degradation was widespread throughout the Site.

The chronology of the Crowns West Project is presented in Table 2. The contact information for all designers, contractors, and relevant suppliers is presented in Table 3. Relevant project background information is presented in Table 4.

2.5 Project Plan

Plans depicting the as-built conditions of the major project elements, locations of permanent monitoring cross-sections, and locations of permanent vegetation monitoring plots are presented in Figures 2A, 2B, 2C, 2D, 2E, 2F and 2G of this report.

3.0 PROJECT CONDITION AND MONITORING RESULTS

3.1 Vegetation Assessment

3.1.1 Description of Vegetative Monitoring

As a final stage of construction, the stream margins and riparian area of the Site were planted with bare root trees, live stakes, and a seed mixture of temporary and permanent ground cover herbaceous vegetation. The woody vegetation was planted randomly six to eight feet apart from the top of the stream banks to the outer edge of the project's re-vegetation limits. In general, bare-root vegetation was planted at a target density of 680 stems per acre, in an 8-foot by 8-foot grid pattern. The tree species planted at the Site are shown in Table 5. The permanent seed mix of herbaceous species applied to the project's riparian area included soft rush (*Juncus effuses)*, redtop (*Agrostis alba),* Virginia wild rye (*Elymus virginicus),* switchgrass (*Panicum virgatum),* smartweed (*Polygonum pennsylvanicum),* tick seed (*Bidens frondosa),* lance leaf coreopsis (*Coreopsis lanceolata*), fox sedge (*Carex vulpinoidea*), hop sedge (C*arex lupulina*), and shallow sedge *(Carex lurida).* This seed mixture was broadcast on the Site at a rate of 15 pounds per acre. All planting was completed in March 2007.

At the time of planting, 11 vegetation plots – labeled 1 through 11 - were delineated on-site to monitor survival of the planted woody vegetation. Each vegetation plot is 0.025 acre in size, or 10 meters x 10 meters. All of the planted stems inside the plot were flagged to distinguish them from any colonizing individuals and to facilitate locating them in the future. The trees also were marked with aluminum metal tags to ensure that the correct identification is made during future monitoring of the vegetation plots.

On a designated corner within each of the eleven vegetation plots, one herbaceous plot was also delineated. The herbaceous plots measure 1 meter x 1meter in size. These plots are photographed at the end of the growing season. The locations of the eleven vegetation plots are presented in Figures 2A through 2G.

3.1.2 Vegetative Success Criteria

To characterize vegetation success criteria objectively, specific goals for woody vegetation density have been defined. Data from vegetation monitoring plots should display a surviving tree density of at least 320 trees per acre at the end of the third year of monitoring, and a surviving tree density of at least 260 five-year-old trees per acre at the end of the five-year monitoring period.

Table 5. Vegetation Species Planted Across the Restoration Site

Crowns West Restoration Site: Project No. D06003-2

Cornus amomum	Silky Dogwood	40%	1,040
Sambucus canadensis	Elderberry	20%	520

3.1.3 Vegetative Observations and Results

The species that were planted as part of the permanent ground cover seed mixture broadcast on the Site after construction were present during Year 4 monitoring of the Site.

Tables A.1. through A.6. in Appendix A present vegetation metadata, vegetation vigor, vegetation damage and stem count data of the monitoring stations at the end of the Year 4 monitoring period. Data from the Year 4 monitoring event of the 11 vegetation plots showed a range of 486 to 972 stems per acre. The data showed that the plots had an average of 659 stems per acre.

Based on these results, all plots are on track to meet the interim success criteria of 260 stems per acre at the end of monitoring Year 5.

Trees within each monitoring plot are flagged regularly to prevent planted trees from losing their identifying marks due to flag degradation. It is important for trees within the monitoring plots to remain marked to ensure they are all accounted for during the annual stem counts and calculation of tree survivability. Permanent aluminum tags are used on surviving stems to aid in relocation and identification during future counts. Flags are also used to mark trees because they do not interfere with the growth of the tree.

No significant volunteer woody species were observed in any of the vegetation plots. The plots will be assessed during Year 5 monitoring for significant volunteer species.

3.1.4 Vegetative Problem Areas

During monitoring Year 3, two problems were observed in vegetation plot 1 that threatened survivability of the plot. These problems were weedy species occurring within the vegetation plot and saturated soils due to beaver dams. The strong presence of arrowleaf tearthumb (*Polygonum sagittatum*) and an unknown vine species in this area was affecting the survivability of the smaller planted stems. Another problem in this area was the presence of two beaver dams that had caused the soils to become saturated for extended periods. This had caused planted stems, mostly sycamores, to become unstable. These trees were observed to be leaning following Year 3 monitoring.

The beaver dams observed in the vegetation plot 1 area were scheduled to be removed in the winter of 2009/2010. Dwayne Huneycutt of Baker met with Mark Batchlor of the United States Department of Agriculture (USDA) on the Site in February 2010. It was noted during the site visit, that the beaver dams observed in the fall of 2009 were not present within the conservation easement. According to Mr. Batchlor of the USDA, it is likely that the beaver have moved off-site. No beaver dams or visible beaver activity were noted in September 2010. This upstream portion of the Site will be closely observed for future beaver activity during Year 5 of monitoring.

Other weedy species are mostly annuals and seem to pose very little threat to survivability on site.

During Year 4 monitoring, kudzu (*Pueraria spp.*) was observed on the Site. The kudzu is located south of Haw Branch Road in the NCDOT right-of-way and also within the project easement. Kudzu within the project easement was treated in September 2008, April 2009 and September 2009 by River Works, Inc. During monitoring Year 4, this area was treated in September 2010. Due to the subsequent treatment events, the kudzu is now under control within the conservation easement and elimination of the invasive plant appears to be possible by the conclusion of Year 5 monitoring in 2011.

Some privet (*Ligustrum L.*) was also observed on the Site, during Year 4 monitoring. The privet is located along the southern easement boundary, west of Haw Branch Road or

along the right side of the restored channel, west of Haw Branch Road. This area of privet was not treated in 2010. This area was previously treated in September 2008, April 2009 and September 2009 by River Works, Inc. Infested areas had been treated in previous years with herbicides and are scheduled to be treated again in 2011.

3.1.5 Vegetation Photographs

Photographs are used to visually document vegetation plot success. A total of 11 reference stations were established to document tree conditions at each vegetation plot across the Site. Additional photo stations were also established at each of the 11 vegetation plots for herbaceous vegetation monitoring. Reference photos of both tree conditions and herbaceous conditions are taken at least once per year. Photos of the tree plots showing the on-site vegetation are included in Appendix A of this report. Photos of the herbaceous plots are also included in Appendix A.

3.2 Stream Assessment

3.2.1 Morphometric Success Criteria

To document the stated success criteria, the following monitoring program was instituted following construction completion on the Site:

Cross-sections: Two permanent cross-sections were installed per 1,000 LF of stream restoration work, with one of the locations being a riffle cross-section and one location being a pool cross-section. A total of nine permanent cross-sections were established across the Site. Each cross-section was marked on both banks with permanent pins to establish the exact transect used. The permanent cross-section pins are surveyed and located relative to a common benchmark to facilitate easy comparison of year-to-year data. The annual cross-section surveys include points measured at all breaks in slope, including top of bank, bankfull, inner berm, edge of water, and thalweg.

The approved Restoration Plan requires the following criteria be met to achieve stream restoration success. There should be little change in as-built cross-sections. If changes do take place, they will be evaluated to determine if they represent a movement toward a more unstable condition (e.g., down-cutting or erosion) or a movement toward increased stability (e.g., settling, vegetative changes, deposition along the banks, or decrease in width/depth ratio). Cross-sections will be classified using the Rosgen Stream Classification System, and all monitored cross-sections should fall within the quantitative parameters defined for channels of the design stream type.

Longitudinal Profiles: A complete longitudinal profile was surveyed following construction completion to record as-built conditions. The profile was conducted for the entire length of the restored channels (M1 and M2). Measurements included thalweg, water surface, bankfull, and top of low bank. Each of these measurements was taken at the head of each feature (e.g., riffle, pool, and glide). In addition, maximum pool depth was recorded. All surveys were tied to a single, permanent benchmark.

As directed by EEP guidelines, longitudinal profiles will be completed in all five years of the monitoring period. The longitudinal profiles should show that the bedform features are remaining stable; i.e., they are not aggrading or degrading. The pools should remain deep, with flat water surface slopes, and the riffles should remain steeper and shallower

than the pools. Bedforms observed should be consistent with those observed for channels of the design stream type.

3.2.2 Morphometric Results

Year 4 cross-section monitoring data for stream stability were collected during October 2010. The nine permanent cross-sections along the restored channels (five located across riffles and four located across pools) were re-surveyed to document stream dimension at the end of monitoring Year 4. Data from each of these cross-sections were compared to data collected during the as-built condition survey, Years 1, 2 and 3 of monitoring. The cross-sectional data are presented in Appendix B. The cross-sections show that there has been very little adjustment to stream dimension since construction.

Cross-sections 1, 3, 4, 7 and 8 are located across riffles found between meander bends. Cross-section 1 has aggraded slightly since the as-built survey but has remained relatively stable through Year 4. The channels in cross-sections 3, 4, 7 and 8 have remained relatively stable since the as-built survey. The floodplains of cross-sections 7 and 8 remained stable through Year 4 monitoring. It was noted during Years 2 and 3 that visual on-site observations of areas east of Haw Branch Road documented deposition of sediment on the floodplain. This is considered to be a natural system response and no areas of concern have been noted due to the deposition.

Cross-sections 2, 5, 6, and 9 are located across pools found at the apex of meander bends. Based on the cross-section data, the pool at cross-section 6 has filled slightly since Year 1 monitoring but has remained relatively stable through Years 2, 3, and 4. It was noted during Year 4 that cross-sections 2, 5 and 9 have remained at or below the as-built thalweg elevations in the maximum pool depths. All pools are remaining deep and seem to be stable.

The longitudinal profiles of reaches M1 and M2 are presented in Appendix B. The longitudinal profile for Year 4 was surveyed in October 2010 and was compared to data collected during the as-built condition survey, and Years 1, 2 and 3 of monitoring. The results of the Year 4 longitudinal profile show that the pools and riffles in M1 have maintained elevations and pool depths, similar to those documented during the as-built survey, and Years 1, 2 and 3 of monitoring. The longitudinal profile shows that the riffles and in-stream structures throughout reach M1 are stable.

The Year 4 profile for M2 shows that the riffles and pools at the beginning of the reach, (stations 33+95 to 42+50) have aggraded slightly since as-built conditions. This section of M2 is showing a tendency to aggrade in drier years (Year 2 and 4) and scour back out in wetter years (i.e. Year 3). This is considered to be a normal pattern of stream bed dynamics within sandbed streams. The Year 4 profile for M2 shows that the pools have remained deep since Year 1. The longitudinal profile for M2 shows that the riffles and in-stream structures are stable on the downstream portion of the reach.

3.2.3 Hydrologic Criteria

One crest gauge was installed on the Site to document bankfull events. The gauge is checked regularly and records the highest out-of-bank flow between site visits. The gauge is located on the downstream portion of reach M2, which is presented in Figure 2G.

The approved Restoration Plan requires that two bankfull flow events must be documented within the five-year monitoring period. The two bankfull events must occur in separate years, otherwise, the stream monitoring will continue until two bankfull events have been documented in separate years.

3.2.4 Hydrologic Monitoring Results

The on-site crest gauge documented the occurrence of at least two bankfull flow events during Year 4 of the post-construction monitoring period, as shown in Table 6. Inspection of conditions during site visits revealed visual evidence of out-of-bank flow, confirming the crest gauge readings. The highest on-site stream flow documented by the crest gauge during Year 4 of monitoring was approximately 3.72 feet (44.64 inches) above the bankfull stage and was the result of overbank flooding of M2. Photographs documenting bankfull evidence observed during Year 4 are presented in Appendix B.

Table 6. Verification of Bankfull Events

Crowns West Restoration Site: EEP Contract No. D06003-2			
Date of Data Collection	**Estimated Date of Occurrence of Bankfull Event**	**Method of Data Collection**	**Measurement (feet)**
2/9/2010	Winter of 2010	Crest Gage on M2	3.51
12/1/2010	9/29/2010	Crest Gage on M2	3.72

The crest gauge on the Site has documented at least one bankfull event per year since as-built conditions. Four bankfull events have been recorded in separate years, which meet the success criteria as stated the site Restoration Plan. The crest gauge readings will continue to be recorded through Year 5 of the project in order to observe flood event depths that may occur on the Site.

3.2.5 Stream Problem Areas

During Year 2 (2008) monitoring, the Site experienced several areas of localized bank erosion. These problems were repaired in November 2008. The stream problem areas were located on reaches M1 and M2. All problems areas were located in pools where erosion occurred around root wads that were installed in sandy soils. During Year 4 these repaired areas were functioning properly and will continue to be monitored closely during future site visits.

During Year 3 monitoring, several additional bank areas on M2 and the lower portion of M1 exhibited small localized, areas of bank erosion, attributed to the number of high flow events during the year and the presence of mostly sandy soils in the identified areas. These areas were small and were not considered to call for repair at this time. However, these areas are being closely observed during site visits. During Year 4 these areas were functioning properly with no further degradation and will continue to be monitored closely during future site visits.

In 2009, two beaver dams on the upstream portion of M1 had caused the soils to become saturated for an extended period. The saturation affected planted stems, mostly sycamores, to lean more than 45 degrees. As of October 2010, the dams are currently not present on the Site. All trees within the vegetation plot that were impacted by the soft soils are currently still alive and are included in the stems totals presented in Table A.1 through A.6. A detailed explanation of the beaver dams and affected areas are discussed in section 3.1.4 of this report.

3.2.6 Stream Photographs

Photographs are used to visually document restoration success. A total of 23 reference stations were established to document conditions at the constructed grade control structures across the Site, and additional photo stations were established at each of the 9 permanent cross-sections. The GPS coordinates of each grade control structure photo station have been noted as additional reference to ensure the same photo location is used throughout the monitoring period. Reference photos are taken at least once per year.

Each stream bank is photographed at each permanent cross-section photo station. For each stream bank photo, the photo view line follows a survey tape placed across the channel, perpendicular to flow (representing the cross-section line). The photograph is framed so that the survey tape is centered in the photo (appears as a vertical line at the center of the photograph), keeping the channel water surface line horizontal and near the lower edge of the frame.

Photographs will be used to document restoration success visually. Reference stations were photographed before construction and will be photographed for at least five years following construction. Reference photos will be taken once per year, from a height of approximately five to six feet. Permanent markers are established to ensure that the same locations (and view directions) on the Site are photographed during each monitoring event. Photos for each of the nine permanent cross-sections are included in Appendix B. A photo log of the restored channel is also presented in Appendix B of this report. Herbaceous vegetation is dense along the edges of the restored stream, making the photography of some of the stream channel areas difficult.

3.2.7 Stream Stability Assessment

A summary of the results obtained from the visual inspection of in-stream structures performed during Year 4 of post-construction monitoring is presented in Table B.1. The percentages noted are a general, overall field evaluation of the how the features were performing at the time of the photo point survey. According to the visual stability assessment, during Year 4 monitoring, some bank areas as described in Section 3.2.5 have experienced some localized erosion problems. Excluding these bank areas, all other stream features are performing as designed.

3.2.8 Quantitative Measures Summary Tables

The quantitative pre-construction, reference reach, and design data used to determine restoration approach, as well as the as-built baseline data used during the project's post construction monitoring period are summarized in Appendix B.

3.2.9 Benthic Macroinvertebrate Sampling

Benthic macroinvertebrate monitoring was conducted in accordance with the Crowns West Restoration Plan. Because of seasonal fluctuations in populations, macroinvertebrate sampling must be consistently conducted in the same season as the initial species evaluations. Benthic sampling for the Site as well as the reference site was conducted during March 2010. This report summarizes the benthic samples collected in March 2010 for Year 3 of the post-construction monitoring phase.

This is the final data collection event for benthic macroinvertebrates for the Site.

The sampling methodology followed the Qual 4 method listed in NCDWQ's Standard Operating Procedures for Benthic Macroinvertebrates (2006). Field sampling was conducted by Michael Baker Engineering, Inc. Laboratory identification of collected species was conducted by Wendell Pennington, of Pennington and Associates, Inc.

Benthic macroinvertebrate samples were collected at one location on the Site (Site 1) and one location at the Beaverdam Branch reference site in Jones County (Site 2). Site 1 is located within the restoration area of M1 on the Site.

Benthic macroinvertebrates were collected to assess quantity and quality of life in the streams. In particular, specimens belonging to the insect orders Ephemeroptera (mayflies), Plecoptera (stoneflies) and Trichoptera (caddisflies), (EPT species) are useful as an index of water quality. These groups are generally the least tolerant to water pollution and therefore are very useful indicators of water quality. Sampling for these three orders is referred to as EPT sampling.

Habitat assessments using NCDWQ's protocols were also conducted at each site. Physical and chemical measurements including water temperature, dissolved oxygen concentration (mg/L), pH, and specific conductivity were recorded at each site. The habitat assessment field data sheets, lab results and photos are presented in Appendix B.

3.2.10 Benthic Macroinvertebrate Sampling Results and Discussion

A comparison between the pre- and post-construction monitoring results is presented in Table 7 with complete laboratory results presented in Appendix B.

At Site 2, the undisturbed reference site, the Year 3 community structure and ecological habitat appears to be similar to that observed during the pre-construction, Year 1 and Year 2 monitoring periods. Site 2 data show a stable total taxa richness and a stable EPT taxa richness. EPT taxa richness at Site 2 has remained relatively stable since Year 1 monitoring. The Year 3 sampling results displayed relatively stable total and EPT biotic indices.

Site 1, which underwent complete restoration, exhibited improvements in total and EPT taxa richness since Year 1 monitoring. According to the lab results, Site 1 showed an improvement in the total biotic index following Year 3 of monitoring. The EPT biotic index following Year 3 has increased from no observed communities to an index 6.36 since March 2006. It is anticipated that, as the project matures, EPT populations will increase as more habitat in the form of snags, logs, and leaf packs become available.

The Year 3 data for the Site displayed 37.5 percent Dominance in Common (DIC) compared to the reference site. This indicates that 37.5 percent of the dominant

communities at the reference site are dominant at Site 1. In pre-construction conditions, Site 1 had a DIC of 41 percent. The DIC result of 37.5 percent at Site 1following Year 3 monitoring, indicates that post-construction recolonization from refugia upstream or downstream, is likely returning to pre-restoration levels. It is anticipated that improvements in biotic indices and an increase in DIC will be seen in as communities begin to re-colonize and the project matures.

Overall, the Year 3 data for Site 1 has displayed substantial improvements in all criteria of the macro invertebrate samples. The Year 3 post-restoration data has shown that the Site has developed from a newly established coastal plain stream system with a weak benthic macroinvertebrate community into a system that exhibits diverse habitats, is continually maturing, and is able to support and cultivate biological diversity.

Table 7. Summary of Pre-Restoration vs. Post-Restoration Benthic Macroinvertebrate Sampling Data

4.0 OVERALL CONCLUSIONS AND RECOMMENDATIONS

Stream Monitoring - The total length of stream channel restored on the Site was 3,835 LF. This entire length was inspected during Year 4 of the monitoring period (2010) to assess stream performance. Visual stability assessments during Years 2 and 3 noted several small, localized erosion areas. Those observed during Year 2 were repaired and those observed during Year 3 did not require repairs. During Year 4 monitoring, all of these areas appear to be stable.

Based on the survey data, all riffles, pools, and other constructed features along the restored channel are stable and functioning as designed. The on-site crest gauge documented the occurrence of at least two bankfull flow events during Year 4 of the post-construction monitoring period. The highest on-site stream flow documented by the crest gauge during Year 4 of monitoring was approximately 3.72 feet (44.64 inches) above the bankfull stage and was the result of overbank flooding of M2. Inspection of site conditions during visits revealed visual evidence of out-of-bank flows.

Overall, the Site is on track to achieve the stream morphology success criteria specified in the Restoration Plan for the Site.

Year 3 macroinvertebrate lab results for the Site, exhibited improvements in total and EPT taxa richness. The total biotic index improved since Year 2 while a decline in the EPT biotic index was observed during Year 3. It is anticipated that, as the project matures, benthic macroinvertebrate populations will increase as more habitat in the form of snags, logs, and leaf packs become available. The DIC result of 37.5 percent at Site 1 following Year 3 monitoring, indicates that post-construction recolonization from refugia upstream or downstream, is likely returning to pre-restoration levels.

Vegetation Monitoring - For the 11 monitoring plots, vegetation monitoring indicated a survivability range of 486 stems per acre to 972 stems per acre with an overall average of 659 stems per acre. The data show that the Site has met the minimum interim success criteria of 320 stems per acre by the end of Year 3 and is on track for meeting the final success criteria of 260 stems per acre by the end of Year 5.

During Year 4 monitoring, kudzu (*Pueraria spp.*) and privet (*Ligustrum L.)* were observed on the Site. These kudzu areas were treated in 2010 and are scheduled to be treated again during the 2011 growing season. The areas of privet were not treated during Year 4, but were previously treated in 2009 and are scheduled for treatment in 2011.

Overall, the site is on track to achieve the vegetative success criteria specified in the Restoration Plan for the Site.

5.0 WILDLIFE OBSERVATIONS

Observations of deer and raccoon tracks are common on the Site. During certain times of the year, frogs, snakes, lizards and crawfish and have been observed.

VEGETATION RAW DATA

VEGETATION TABLES

Table A.1. Vegetation Metadata

Crowns West Restoration Site: Project No. D06003-2

Report Prepared By	Dwayne Huneycutt
Date Prepared	9/23/2010 15:03
database name	cvs-eep-entrytool-v2.2.7_2009.mdb
database location	L:\Monitoring\Veg Plot Info\CVS Data Tool\Crowns West\Year 4
computer name	CARYWDHUNEYCU2
file size	36347904
DESCRIPTION OF WORKSHEETS IN THIS DOCUMENT----------	
Metadata	Description of database file, the report worksheets, and a summary of project(s) and project data.
Proj, planted	Each project is listed with its PLANTED stems per acre, for each year. This excludes live stakes.
Proj, total stems	Each project is listed with its TOTAL stems per acre, for each year. This includes live stakes, all planted stems, and all natural/volunteer stems.
Plots	List of plots surveyed with location and summary data (live stems, dead stems, missing, etc.).
Vigor	Frequency distribution of vigor classes for stems for all plots.
Vigor by Spp	Frequency distribution of vigor classes listed by species.
Damage	List of most frequent damage classes with number of occurrences and percent of total stems impacted by each.
Damage by Spp	Damage values tallied by type for each species.
Damage by Plot	Damage values tallied by type for each plot.
Planted Stems by Plot and Spp	A matrix of the count of PLANTED living stems of each species for each plot; dead and missing stems are excluded.
PROJECT SUMMARY----------

Table 1. Taxa list and abundance for benthic macroinvertebrates collected By Baker Engineering, Crowns West and Beaverdam Branch, Onslow/Jones Counties, 10 March 2010. Crowns West is a restoration site; Beaverdam Branch is a reference site. A=Abundant, C=Common, R=Rare

Taxon	TV	Crowns W	Beaverdam
EPHEMEROPTERA			
Leptophlebia sp	6.2	R	-
Pseudocloeon frondalis	7.5	C	C
Pseudocloeon propinquous	5.8	C	R
Baetis intercalaris	7.0	-	C
Maccaffertium modestum	5.5	-	A
Stenacron interpunctatum	6.9	-	R
TRICHOPTERA			
Cheumatopsyche spp	6.2	A	A
COLEOPTERA			
Gyrinus sp	6.2	R	C
Dineutus sp	5.5	-	R
Helichus sp	4.6	-	C
Enochrus sp	8.8	-	R
ODONATA			
Calopteryx sp	7.8	-	A
Ischnura sp	9.5	-	C
Pachydiplax longipennis	9.9	R	-
MEGALOPTERA			
Nigronia serricornis	5.0	-	R
DIPTERA: MISCELANEOUS			
Tipula spp	7.3	-	R
Simulium spp	6.0	A	C
S. ubiquitum	-	A	A
S. venustrum gr	7.1	C	-
Chrysops sp	6.7	R	R
DIPTERA: CHIRONOMIDAE			
Microtendipes sp	5.5	-	R
Polypedilum aviceps	3.7	-	C
Polypedilum fallax	6.4	-	R
Rheotanytarsus sp	5.9	R	-
Conchapelopia group	8.4	R	C
Corynoneura sp	6.0	-	R
Eukiefferiella claripennis gr	5.6	R	-
Cricotopus bicinctus	8.5	C	C
C. patens	-	R	-
Orthocladius obumbratus gr	8.5	C	A
O. oliveri	-	A	-
Parametricnemus lundbecki	3.7	R	R

Taxon	TV	Crowns W	Beaverdam
CRUSTACEA			
Procambarus sp	7.0	R	-
Crangonyx sp	7.9	R	-
Gammarus fasciatus	9.1	-	A
Hyalella azteca	7.8	-	R
Caecidotea racovitzai	5.5	-	R
MOLLUSCA			
Physella spp	8.8	-	C
OTHER			
Ranatra sp (Hemiptera)	7.8	-	R
Summary Metrics			
Total Taxa Richness		19	31
EPT taxa Richness		4	6
EPT Abundance		17	28
NC Biotic Index		6.6	6.2
Seasonally corrected		6.8	6.4

Notes

-All sites are assumed to be too small for a rating, although the abundance of Hydropsychidae (which require flowing water) at both sites indicated that these streams could support a more normal lotic macroinvertebrate community.

-The Biotic Index values for Crowns West would be in the Fair range for Coastal Plain streams >4 meters wide, while Beaverdam Br would be in the Good-Fair range. Low EPT taxa richness for Crowns West also suggested lower water quality, esp. the absence of *Maccaffertium*

-The much higher taxa richness at the reference site may reflect a higher habitat diversity.

Site 1 – Crowns West macroinvertebrate sampling site, view is upstream (Year 3)

Site 1 – Crowns West macroinvertebrate sampling site, view is downstream (Year 3)

Site 2 – Beaverdam Branch macroinvertebrate sampling site, view is upstream (Year 3)

Habitat Assessment Field Data Sheet
Coastal Plain Streams

TOTAL SCORE 91

Biological Assessment Unit, DWQ
Directions for use: The observer is to survey a **minimum of 100 meters with 200 meters preferred** of stream, preferably in an **upstream** direction starting above the bridge pool and the road right-of-way. The segment which is assessed should represent average stream conditions. To perform a proper habitat evaluation the observer needs to get into the stream. To complete the form, select the description which best fits the observed habitats and then circle the score. If the observed habitat falls in between two descriptions, select an intermediate score. A final habitat score is determined by adding the results from the different metrics.

Stream Beaverdam Br. Location/road: Site 2 (Road Name Davis Field) County Jones

Date 3-18-10 **CC#** _____ Basin Neuse Subbasin 03-04-11

Observer(s) DH, RD Type of Study: ☐ Fish ☑ Benthos ☐ Basinwide ☐ Special Study (Describe) _____

Latitude _____ Longitude _____ Ecoregion: ☑ CA ☐ SWP ☐ Sandhills ☐ CB

Water Quality: Temperature 14.3 °C DO 9.30 mg/l Conductivity (corr.) 240 µS/cm pH 6.60

Physical Characterization: Visible land use refers to immediate area that you can see from sampling location. Check off what you observe driving thru the watershed in watershed land use.

Visible Land Use: 60 %Forest ✓ %Residential ✓ %Active Pasture ✓ % Active Crops
_____%Fallow Fields _____% Commercial _____%Industrial _____%Other - Describe: _____

Watershed land use ☐ Forest ☑ Agriculture ☐ Urban ☐ Animal operations upstream

Width: (meters) Stream 2m Channel (at top of bank) 2m **Stream Depth**: (m) Avg _____ Max ____
☐ **Width variable** ☐ **Braided channel** ☐ **Large river >25m wide**
Bank Height (from deepest part of channel to top of bank): (m) 1m

Flow conditions : ☐High ☐Normal ☐Low
Channel Flow Status
Useful especially under abnormal or low flow conditions.

A. Water reaches base of both banks, minimal channel substrate exposed	☐
B. Water fills >75% of available channel, or <25% of channel substrate is exposed	☑
C. Water fills 25-75% of available channel, many logs/snags exposed	☐
D. Root mats out of water	☐
E. Very little water in channel, mostly present as standing pools	☐

Turbidity: ☐Clear ☐ Slightly Turbid ☐Turbid ☐Tannic ☐Milky ☐Colored (from dyes) ☐Green tinge
Good potential for Wetlands Restoration Project?? ☐ **YES** ☐ **NO**
Details N/A

☐Channelized ditch
☐Deeply incised-steep, straight banks ☐Both banks undercut at bend ☐Channel filled in with sediment
☐Recent overbank deposits ☐Bar development ☐Sewage smell
☐Excessive periphyton growth ☐Heavy filamentous algae growth

Manmade Stabilization: ☐N ☐Y: ☐Rip-rap, cement, gabions ☐ Sediment/grade-control structure ☐Berm/levee
