EXECUTIVE SUMMARY

The East Buffalo Creek site was restored through a full delivery contract with the NCDENR – Division of Mitigation Services (DMS). This report documents the completion of the project and presents Year 4 monitoring data for the five-year monitoring period. The goals for the restoration project were as follows:

- To create geomorphically stable conditions on the East Buffalo Creek project site;
- The reduction of sediment loading through restoration of riparian areas and streambanks;
- To improve and restore hydrologic connections between the creek and floodplain;
- The restoration and preservation of headwater tributaries draining into East Buffalo Creek (and Lake Santeetlah); and
- To improve aquatic and terrestrial habitat along the project corridor.

To accomplish these goals, the following objectives were implemented:

- Restoration of incised, eroding, and channelized streams by creating a stable channel that has access to its floodplain;
- Relocate the perched stream channel from the side slope ditch to the low point of the valley to restore natural hydrology and geomorphic form;
- Improve water quality by establishing buffers for nutrient removal from runoff; relocating an eroded, unpaved driveway away from the stream channel and out of the riparian buffer to minimize the sediment supply to the stream; and by stabilizing stream banks to reduce bank erosion;
- Improve in-stream habitat by providing a more diverse bedform with riffles and pools, creating deeper pools, developing areas that increase oxygenation, providing woody debris for habitat, and reducing bank erosion; and
- Improve terrestrial habitat by removing invasive species, planting riparian areas with native vegetation and protecting these areas with a permanent conservation easement so that the riparian area will increase storm water runoff filtering capacity, improve bank stability, provide shading to decrease water temperature and improve wildlife habitat.

Three vegetation monitoring plots, 100 square meters (m^2) (10m x 10m) in size, were used to estimate survival of the woody vegetation planted on-site. The Year 4 vegetation monitoring indicated an average survival of 809 planted stems per acre and 459 volunteer stems per acre were present in plots, for an average density in monitoring plots of 1,268 woody stems per acre. The data shows that the Site has met the interim stem survival criteria for Year 3 (320 stems per acre) and is on track to meet the final success criteria of 260 trees per acre by the end of Year 5.

The design implemented at the East Buffalo Creek mitigation project site involved Priority Level 1 Restoration, and Enhancement Levels I and II approaches. The resulting design will ultimately yield a stable A-B type channel for UT2 to East Buffalo Creek and a B-type channel on Reach 3 of UT6 to East Buffalo Creek. Restoration and enhancement work were completed in accordance with the approved design approach provided in the mitigation plan for East Buffalo Creek and its tributaries. Longitudinal profile and cross-section data indicate that the project streams have remained stable since baseline monitoring data were collected in February 2011. Additionally, as the photo logs included in this report show, the herbaceous cover at the project site is flourishing and is promoting bank stability on-site while planted woody vegetation becomes more established. Based on geomorphic data presented in Appendix B and D, this Site is currently on track to meet the hydrologic and stream success criteria specified in the East Buffalo Creek Mitigation Plan. One issue at the site is that flow through the restored UT2 reach is not entirely at the surface of the reach; the length of channel with surface flow had increased annually through the February 2014 monitoring period flow; however, little change has occurred during this past year. Surface flow was observed for over half of the reach. The only other issue is the presence of invasive vegetation, specifically Multiflora Rose and Chinese Privet, along portions of Reaches 2 of UT5, UT6, and East Buffalo Creek. These areas have been treated a number of times since the project began.

Treatment during 2014 appears to have significantly reduced the density of invasive vegetation in many areas. The remaining invasives have persisted after previous treatments; however, treatment of invasives in the project easement will continue this year.

Summary information and statistics related to performance of various project and monitoring elements can be found in the tables and figures in the report appendices. Narrative background and supporting information formerly found in these reports can be found in the Baseline Monitoring Report (formerly Mitigation Plan) and in the Mitigation Plan (formerly Restoration Plan) documents available on DMS's website. All raw data supporting the tables and figures in the appendices is available from DMS upon request.

1.0 PROJECT BACKGROUND AND ATTRIBUTES

The East Buffalo Creek mitigation site is located approximately three miles north of Robbinsville in Graham County, North Carolina (Figure 1, Appendix A). The project site is situated in the Little Tennessee River Basin, within North Carolina Division of Water Quality (NCDWQ) sub-basin 04-04-04 and United States Geologic Survey (USGS) hydrologic unit 06010204020030. The East Buffalo Creek mitigation project is located in a watershed that is predominantly forested but also contains a small number of residences near East Buffalo Creek and its tributaries. The vast majority of the watershed is in forested cover, with less than one percent of land being in open grassland. Over the past 100 years, various parcels of property on the lower slopes and valley bottom have been developed for residential and agricultural use including the hillside where UT2 is located.

The majority of the project site consists of forested uplands with a smaller proportion devoted to an abandoned pasture. Although the project watershed has been impacted by logging activity and pasture development 100 or more years ago, most of the watershed has returned to a more natural state. The present landowners currently maintain several acres as grassland; however, since the beginning of the project some of this area has not been mowed. There are three single-family residences located in the vicinity of the project streams.

During development of the land for agricultural and residential use, the lower reaches of East Buffalo Creek and three of its tributaries (UT2, UT5 and UT6), were impacted by channel relocation, channelization, and pasture conversion. The project area has also been impacted by the development of a long driveway that provides access to one of the homes and property, riparian vegetation removal, and the installation of culverts on portions of East Buffalo Creek and its tributaries. The effects of these practices over time led to a decrease of in-stream habitat quality from a combination of changes, including channel incision, channel aggradation and embeddedness, reduced baseflow elevation (from disconnected hydrology), proliferation of invasive species within the riparian buffer, and reduced channel shading. Widespread or systemic channel incision has been limited by a combination of grade control structures like exposed bedrock, large cobble and boulder substrate that is frequently found throughout these stream systems. Existing woody vegetation along stream banks has kept portions of the banks from eroding although some channel erosion was present where woody vegetation had been removed.

The project involved restoration or enhancement of 2,987 linear feet (LF) of four streams: East Buffalo Creek and three smaller unnamed tributaries (UT2, UT5 and UT6). In addition, 8,558 LF of East Buffalo Creek and other headwater tributaries were preserved. The restoration, enhancement, and preservation of 11,545 LF of stream within this project site has generated 3,311 stream mitigation units (SMUs); 535 SMUs, or 16 percent of the total generated, were derived from intermittent streams, which is well within the 20 percent threshold required by DMS. Other general information about the project is provided in Tables 1-4 (Appendix A).

1.1 Location and Setting

The East Buffalo Creek mitigation site is located approximately three miles north of Robbinsville in Graham County, North Carolina. To reach the project site from Robbinsville, take U.S. Highway 129 north for approximately three miles and turn right on to East Buffalo Circle (SR1144). Continue on East Buffalo Circle for about a half mile and turn right on East Buffalo Road (SR1254) and continue to the end. East Buffalo Road transitions to a gravel road; the site is accessible from a gated private driveway located .18 miles past where the road becomes gravel and just past the driveway to a brick home.

2.0 METHODOLOGY AND RESULTS

The five-year monitoring plan for the East Buffalo Creek mitigation project includes criteria to evaluate the success of the vegetation and stream components of the project. The specific locations of vegetation plots, permanent cross-sections, reference photo stations and crest gauges are shown on the Year 4 current condition plan view (CCPV) submitted with this report.

2.1 Stream Assessment

2.1.1 Morphologic Parameters and Channel Stability

Geomorphic monitoring of restored stream reaches is being conducted over a five year period to evaluate the effectiveness of the restoration practices installed. Monitored stream parameters include channel dimension (cross-sections), profile (longitudinal survey), pattern (to a lesser degree for reasons noted below), bed composition, bank stability, bankfull flows, and stability of reference sites documented by photographs. Crest gauges, as well as high flow marks, will be used to document the occurrence of bankfull events. The methods used and any related success criteria are described below for each parameter. For monitoring stream success criteria, eight permanent cross-sections, two longitudinal profile sections, multiple photo points and two crest gauges were installed.

2.1.1.1 Dimension

Eight permanent cross-sections were installed to help evaluate the success of the mitigation project. Permanent cross-sections were established throughout the project site as follows: four cross-sections were located on UT2, and four cross-sections were located on Reach 3 of UT6. Cross-sections selected for monitoring were located in representative riffle and pool reaches and each cross-section was marked on both banks with permanent pins to establish the exact transect used. A common benchmark will be used for cross-sections and consistently referenced to facilitate comparison of year-to-year data. The cross-sectional surveys will include points measured at all breaks in slope, including top of bank, bankfull, inner berm, edge of water, and thalweg, if the features are present. Riffle cross-sections were classified using the Rosgen Stream Classification System.

There should be little change in the as-built cross-sections. If changes do take place, they will be evaluated to determine if they represent movement toward a more unstable condition (e.g., down-cutting or erosion) or movement toward increased stability (e.g., settling, vegetative changes, or deposition along the banks).

2.1.1.1.1 Results

As-built cross-section monitoring data for stream stability was collected in April 2011. The eight permanent cross-sections: four along the restored channel and four along the enhanced reach of UT6, were re-surveyed to document any changes to stream dimension during Monitoring Year 4. Cross-sectional data is presented in Exhibit 3 and Table 8 of Appendix D. The location of cross-sections is shown on the current condition plan view submitted with this report.

The cross-sections show that there has been little adjustment to stream dimension across the project reaches since construction. Cross-section 1 on UT2 indicates a small change in depth occurred after the first two years of the project, whereas the other cross-sections indicate little change. At this time, cross-sectional measurements do not indicate any streambank or channel stability issues.

As noted in the Stream Reach Morphology Data Table for Reach 3 of UT6 in Appendix D (Table 9), average bank height ratios for cross-sections along this reach are approximately twice as high as that specified for design; the average bank height ratio from the as-built and monitoring surveys was 1.9 to 2.1 compared to 1.0 from design. The design originally proposed isolated flood plain benching along the left bank where the top of bank would have coincided with the bankfull bench elevation thereby resulting in the proposed design bank height ratio of 1.0. However, to conform to the channel shape or geometry of pre-existing stable portions of the reach both upstream and downstream of the enhancement reach, banks were sloped back accordingly during construction instead, and stabilized with boulders for toe protection. A bank height ratio of 2.0 tends to be an indicator of an incised channel but the average entrenchment ratio reported for Reach 3 is 1.7, which fulfills the stable design specifications of a B-type Rosgen channel classification. The inflated bank height ratio of 1.9 along this reach is due to the steepness associated with the stream and the existing top of road embankment and valley wall, which serve to function as the top of left and right banks of Reach 3 respectively.

2.1.1.2 Pattern and Longitudinal Profile

Longitudinal profiles for Year 4 were surveyed during November 2014; profiles of the various project reaches are provided in Appendix D. A longitudinal profile was conducted for the entire project length on UT2 and Reach 3 of UT6. Longitudinal profiles will be replicated annually during the five year monitoring period.

Measurements taken during longitudinal profiles include thalweg, water surface, and top of low bank. The pools should remain relatively deep with flat water surface slopes, and the riffles should remain steeper and shallower than the pools. Bed form observations should be consistent with those observed for channels of the design stream type. Profile data collected reflect stable channel bedform and a diverse range of riffle and pool complexes.

All measurements were taken at the head of each feature (e.g., riffle, run, pool, glide) and the maximum pool depth. Elevations of grade control structures were also included in the longitudinal profiles surveyed. Surveys were tied to a permanent benchmark. Although pattern adjustments were made on UT2 for channel alignment considerations such as following the low point of the valley, pattern adjustments were not made with the intent to increase sinuosity. East Buffalo Creek and its tributaries are A and B-type streams primarily characterized by step-pool sequences. Consequently, pattern information is not provided in Appendix D as the parameters present are generally associated with meandering, riffle-pool channels. However, as the site is monitored, reaches will be evaluated for significant changes in pattern. Any changes that occur, which warrant repair, will be discussed in future monitoring reports.

2.1.1.2.1 Results

The longitudinal profiles show that the bed features are stable; closely-spaced grade control structures continue to help maintain the overall profile desired. As noted in the Stream Reach Morphology Data Tables in Appendix D (Table 9), riffle and pool characteristics do not appear to have significantly changed since construction; the measurements obtained for Year 4 are acceptable when compared to reference reach and design data provided for the project reaches. Step-pools and riffles appear to have adjusted slightly in some areas of UT6-Reach 3, but such adjustments are considered to be acceptable and expected given the natural steepness of the channel in this location and the amount of large cobbles and small boulders moving in the stream. The Enhancement Level 1 approach which included adding grade control to improve pool habitat has also enhanced the vertical stability of this reach.

There was also little to no change in the profile of UT2 to East Buffalo Creek. Although the profile appears stable, there is a section of UT2 where the stream flow goes subsurface; this section is illustrated on the current condition plan view and documented in Tables 11 and 12 in

Appendix F. Given the steepness in slope and the relatively large riffle material used to construct the step-pool channel system, it is likely that the flow will remain subsurface until interstitial spaces between the stones of the constructed channel bed become filled by smaller particles and organic material. Particle sorting was observed in the channel during the Year 3 & 4 survey, indicating that there is flow in the channel at times. However, the presence of rooted plant material indicates that the baseflow remains under the bed material most of the time. During the 2013-2014 monitoring period, it was observed during at least 3 different visits to the site that surface flow was continuous over approximately half of the restored reach. This was also observed during visits for Year 4 monitoring. This distance over which flow is at the surface appears to be increasing and we believe that in time it will continue across the reach. The subsurface flow condition on UT2 will be monitored and managed as we assess the progress of this surface flow condition. No areas of instability were noted during Year 4 monitoring.

2.1.1.3 Substrate and Sediment Transport

Bed load material analysis consists of a pebble count taken in the same constructed riffle during annual geomorphic surveys of the project site. This sample, combined with evidence provided by changes in cross-sectional and profile data will reveal changes in sediment gradation that occur over time as the stream adjusts to upstream sediment loads. Significant changes in sediment gradation will be evaluated with respect to stream stability and watershed changes.

2.1.1.3.1 Results

For this project, a pebble count was collected on UT6. Visual observations of UT6 and a review of pebble count data collected during Year 4 monitoring did not yield any signs that sediment transport functions have been hampered by the mitigation project; specifically, no significant areas of aggradation or degradation within the project area were observed. The pebble count data (Table 9, Appendix D) indicates that the stream is moving fines through the system and larger pebbles continue to make up a greater percentage of the bed material. However, the Year 4 pebble count yielded bed particles that were somewhat smaller than last year's sample though not greatly different.

2.1.2 Hydrology

2.1.2.1 Streams

The occurrence of bankfull events within the monitoring period will be documented by the use of crest gauges and photographs. Crest gauges were installed on the floodplain at the bankfull elevation. One crest gauge was placed on UT2 while another gauge was set up near the end of the project area on Reach 3 of UT6. The crest gauges record the highest watermark between site visits and are checked at each site visit to determine if a bankfull event has occurred. Photographs are used to document the occurrence of debris lines and sediment deposition on the floodplain during monitoring site visits.

Two bankfull flow events must be documented on each crest gauge within the 5-year monitoring period. The two bankfull events must occur in separate years; otherwise, the stream monitoring will continue until two bankfull events have been documented in separate years or until the monitoring period ends. If two bankfull events have not been documented at the end of 5 years the IRT will have to decide on an appropriate course of action.

2.1.2.1.1 Results

During the Year 4 monitoring period, the site was found to have had at least one bankfull event based on crest gauge readings obtained on both UT2 and UT6 of East Buffalo Creek. Since project completion, UT2 has had three recorded bankfull events, and UT6 has had four recorded bankfull events during different years for each site. Information on these events is provided in Table 10 of Appendix E. At this point in the monitoring period more than two bankfull flow

events have been documented on each crest gauge within the 5-year monitoring period. The hydrology success criterion has been met; however, we will continue to monitor the crest gauges for the Year 5 monitoring period.

2.1.3 Photographic Documentation of Site

Photographs will be used to document restoration success visually. Reference stations were photographed during the as-built survey; this will be repeated for at least five years following construction. Reference photos are taken once a year, from a height of approximately five to six feet. Permanent markers will ensure that the same locations (and view directions) are utilized during each monitoring period. Selected site photographs are shown in Appendix B.

2.1.3.1 Lateral Reference Photos

Reference photo transects were taken of the right and left banks at each permanent cross-section. A survey tape was captured in most photographs which represents the cross-section line located perpendicular to the channel flow. The water line was located in the lower edge of the frame in order to document bank and riparian conditions. Photographers will make an effort to consistently maintain the same area in each photo over time.

2.1.3.2 Structure Photos

Photographs of primary grade control structures (i.e. vanes and weirs), along the restored streams are included within the photographs taken at reference photo stations. Photographers will make every effort to consistently maintain the same area in each photo over time.

Lateral and structure photographs are used to evaluate channel aggradation or degradation, bank erosion, success of riparian vegetation, structure function, and stability, and effectiveness of erosion control measures subjectively. Lateral photos should not indicate excessive erosion or degradation of the banks. A series of photos over time should indicate successive maturation of riparian vegetation and consistent structure function. Photo documentation of the site during Year 4 monitoring reflects stable site conditions in restored or enhanced areas as well as a healthy stand of herbaceous and woody vegetation in the riparian corridors.

2.1.3.2.1 Results

Photographs of the restoration project were taken in March 2015. The photographs illustrate stable conditions across the project site. Vegetative growth along the streambanks and riparian buffers has become dense and improved since construction was completed in 2011. Structures are functioning as designed.

2.1.4 Stream Stability Assessment

In-stream structures installed within the restored streams included log drops, rock drops, log/rock drop sequences, boulders, and boulder steps. The Year 4 visual observations of these structures indicate that little or no changes have occurred since the baseline survey was performed; structures are functioning as designed and are holding their elevation and grade. Evidence of flow through this segment of channel during Year 4 did not result in any vertical stability issues. Structures located in Reach 3 of UT6 are also functioning as intended to provide supplemental grade control while enhancing pool habitat. Table 11 in Appendix F provides a comprehensive visual assessment of morphological stability throughout both UT2 and Reach 3 of UT6.

Quantitative reference reach and design data used to determine the restoration approach, as well as the Year 4 data collected during the project's post-construction monitoring period are summarized in Appendix D.

2.2 Vegetation Assessment

2.2.1 Vegetation

Successful restoration of the vegetation on a site is dependent upon hydrologic restoration, active planting of preferred canopy species, and volunteer regeneration of the native plant community. In order to determine if the success criteria are achieved, three vegetation monitoring quadrants were installed across the restoration site. The size of individual quadrants varies from 100 square meters for tree species to 1 square meter for herbaceous vegetation. Level 1 CVS vegetation monitoring will occur in spring, after leaf-out has occurred, or in the fall. At the end of the first growing season during baseline surveys, species composition, density, and survival were evaluated. Individual quadrant data provided during subsequent monitoring events will include diameter (dbh), height, density, and coverage quantities. Relative values will be calculated, and importance values will be determined. Individual seedlings will be marked to ensure that they can be found in succeeding monitoring years. Mortality will be determined from the difference between the previous year's living, planted trees and the current year's living, planted trees.

Photographs are used to visually document vegetation success in sample plots. Reference photos of tree and herbaceous condition within plots are taken at least once per year. Photos of the plots are included in Appendix B of this report.

The interim measure of vegetative success for the site is the survival of at least 320, 3-year old, planted trees per acre at the end of Year 3 of the monitoring period. The final vegetative success criteria is the survival of 260, 5-year old, planted trees per acre at the end of monitoring Year 5.

Temporary seeding, applied to streambanks beneath the erosion matting, sprouted within two weeks of application and has provided excellent ground coverage. Planted live stakes and bare root trees are also flourishing and will increasingly contribute to streambank stability. Bare-root trees were planted throughout the conservation easement with the exception of the preservation reach. A minimum 30-foot buffer was established along all restored stream reaches. In general, bare-root vegetation was planted at a target density of 680 stems per acre, in an 8-foot by 8-foot grid pattern. Planting of bare-root trees was completed in late March-early April 2011. Species planted are listed below.

The mitigation plan for the East Buffalo Creek Site specifies that the number of quadrants required will be based on the species/area curve method, as described in DMS monitoring guidance. The size of individual quadrants is 100 square meters for woody tree species, and 1 square meter for herbaceous vegetation. Three vegetation plots, each 10 by 10 meters or 5 by 20 meters in size, were established across the restored site.

2.2.1.1.1 Results

Tables 5 through 7b in Appendix C presents information on plots meeting the vegetation success criteria, vegetation metadata, and stem counts for each of the vegetation monitoring plots. Data from the Year 4 monitoring event showed a range of 728 to 931 stems per acre, with approximately 90.7% of the stems being in good to excellent condition. The average density of planted stems, based on data collected from the three monitoring plots during Year 4 monitoring, is 809 stems per acre, or about 19 stems per plot. The site was originally planted at an average density of approximately 1,052 bare root stems per acre after construction (as cited in the Baseline Monitoring Document), or about 26 stems per plot. The average volunteer stems per acre, based on counts within the plots, was estimated to be 459 stems per acre. When planted and volunteer stems are combined plots supported an average of 1,268 stems per acre. It should be noted that if volunteer stems exceeded 10 per plot/species only 10 were used in the density estimates. With an average density of 320 trees per acre by the end of Year 3, and is on track to meet the final success criteria of 260 trees per acre by the end of Year 5. The location of the vegetation plots are shown on the Year 4 current condition plan view (Figure 3 of Appendix F).

There were three vegetation problem areas identified during Year 4 monitoring that related to the presence of invasive vegetation along Reaches 2 of UT5, UT6, and East Buffalo Creek. Multiflora Rose and Chinese Privet found along portions of these reaches appear to primarily be a result of invasives that have persisted after prior treatment. We have retained the same areas of concern that were reported last year in this year's report; however, a significant reduction in the density of invasives has been made in these areas as evidenced by the photos that are presented (Appendix F). The large area of withered and dead Muliflora Rose and Chinese Privet observed along these reaches, especially along UT5 Reach 2, is indicative that prior spray treatment was effective for much of the cover. However, the current extent of persistent invasives (CCPV in Appendix F) warrants immediate follow-up treatment to limit potential proliferation and will be scheduled to be conducted in the spring and summer of 2015; an updated status of these vegetation problem areas will be provided in the Year 5 monitoring report.

Although the density of herbaceous cover varies across the site, conditions observed on-site during the Year 4 monitoring survey found ground cover in the easement area to be sufficient for stabilizing the site and for providing good terrestrial habitat. Survival rates of planted woody stems in the vegetation plots indicate that plantings across the easement area are of sufficient density to meet regulatory requirements, site stabilization and habitat enhancement goals originally set forth in the mitigation plan.

2.3 Areas of Concern

At this time, the only items that are being monitored beyond the success criteria noted in this report is the dry segment of UT2 and the invasive vegetation problem areas documented on Reaches 2 of UT5, UT6, and East Buffalo Creek. As noted in Section 2.1.1.2 of the Baseline Monitoring Report, we believe that the surface flow of UT2 is presently flowing beneath and through the channel bed material along the lower half of the restored reach. This is not unusual for steep, rocky, low flow channels in this area. The flow along UT2 should surface as organic material and fine particles reduce interstitial spaces in the constructed channel. We plan to add fine grain material to this channel in the spring of 2015 to promote the closing off of interstitial spaces and activation of surface flow. We will continue to monitor the flow condition of UT2 and the presence of invasives on Reaches 2 of UT5, UT6, and East Buffalo Creek, and manage these reaches as seems most appropriate. Baker will provide an updated status of these stream and vegetation problem areas in the Year 5 monitoring report.

APPENDIX A FIGURE & GENERAL TABLES

> LOCATION MAP TABLES 1-4

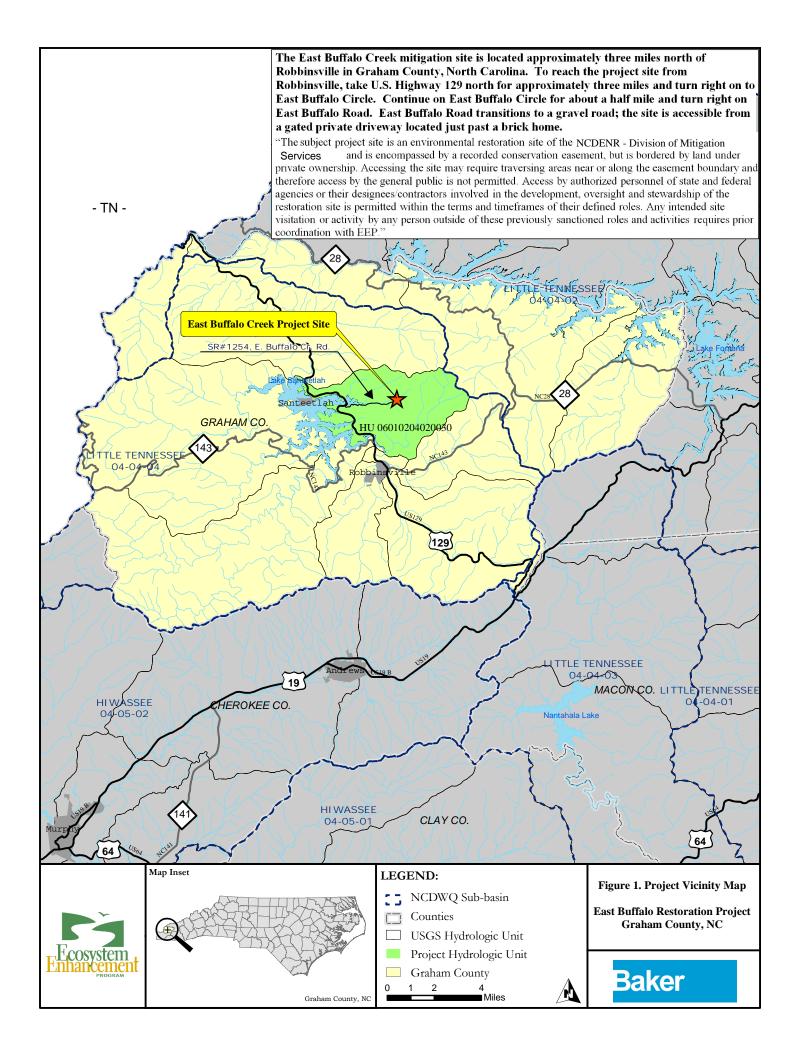

Figure 1. Notes

The East Buffalo Creek mitigation site is located approximately three miles north of Robbinsville in Graham County, North Carolina. To reach the project site from Robbinsville, take U.S. Highway 129 north for approximately three miles and turn right on to East Buffalo Circle. Continue on East Buffalo Circle for about a half mile and turn right on East Buffalo Road. East Buffalo Road transitions to a gravel road; the site is accessible from a gated private driveway located just past a brick home.

The subject project site is an environmental restoration site of the NCDENR - Division of Mitigation Services (DMS) and is encompassed by a recorded conservation easement, but is bordered by land under private ownership. Accessing the site may require traversing areas near or along the easement boundary and therefore access by the general public is not permitted. Access by authorized personnel of state and federal agencies or their designees/contractors involved in the development, oversight and stewardship of the restoration site is permitted within the terms and timeframes of their defined roles. Any intended site visitation or activity by any person outside of these previously sanctioned roles and activities requires prior coordination with DMS.

FIGURE 2 PROJECT COMPONENT MAP EXHIBIT 1-2 REFERENCE STATION AND VEGETATION PLOT PHOTOLOGS

East Buffalo Creek Photo Log – Preservation Reference Photo Points

Notes: Photos for East Buffalo Creek were taken March 2015.

- 1. Photo point locations are shown on the plan sheets in the actual location the picture was taken.
- 2. All points are marked with flagging and recorded with GPS points. For channel points, the flagging is tied on an adjacent bank.

¹ Thalweg feature is scored according to the centering of the thalweg over inverts of drop structures above pools and through the constructed riffle below pools since this reach is a step-pool channel without meander bends.

² Vane feature category was replaced with rock/log drop structures since there are no vanes present on this reach. ³ While all structures that had surface flow were functioning well, flow over much of the channel is still subsurface. During the survey of the channel this and many other area channels were dry; however, during later visits to the site we discovered flow extended to approximately the same point as it had in 2014 and then went subsurface, resurfacing at the lower end of the reach, as it had last year.
