EXECUTIVE SUMMARY

The Farrar Dairy Site is located in the Sand Hills physiographic province in Harnett County, North Carolina. The project will provide mitigation for stream and wetland impacts within the 8-digit hydrologic cataloging unit 03030004 in the Cape Fear River Basin by restoring, enhancing, and preserving 13,044 linear feet of stream and 112 acres of wetland, generating 11,881 stream mitigation units (SMU's) and 64.06 wetland mitigation units (WMU's). The goals of the project include restoring the riparian buffers and forested wetlands as well as creating a stable stream and wetland complex through an interconnected floodplain corridor. In order to achieve these goals, the project objectives included connecting the new stream planform to its original floodplain, filling and plugging ditches in the drained hydric soils to restore saturated hydrologic conditions, planting a functional Coastal Plain Small Swamp Stream community to create an effective riparian buffer and wetland complex, and removing cattle from the riparian areas with livestock exclusion fencing.

The project watershed drains from the northeast toward the southeast with a contributing area of approximately 5.7 square miles at the downstream limits. The rural watershed faces low to moderate development pressure from the surrounding area. The stream and wetland design along with the restoration plan were completed in May 2008, construction began in October 2008, and the site was planted prior to the 2009 growing season.

The stream restoration included eight separate reaches, which were either enhanced or restored using a combination of Priority 1 and 2 approaches. The wetland mitigation is comprised of five areas that combine preservation, enhancement, and restoration. In-stream structures, such as step pools and log drops were used to control grade throughout the restored stream's profile. The main channel through the site, the North Prong of Anderson Creek (NPAC), was restored to a C5 type channel, while its associated tributaries were restored or enhanced to C5/B5c, E5, and C5 type channels. The as-built survey and baseline monitoring found only minimal deviations from the designed cross-sections and profile. During construction, several large rain events caused minor problem areas on the restored stream channels. These issues and the repairs associated with them caused some small alterations to the stream profiles and dimension. These changes have been recorded on the as-built site plan. Since construction, the site has become well vegetated and the streams have remained stable throughout the storm events that have occurred since construction was completed.

The wetlands on the site were restored, enhanced, and preserved. The Priority 1 stream restoration restored the hydrology to the wetlands adjacent to the stream. Along with the restoration of these previously drained wetlands, other wetlands were enhanced by removing berms, treating invasive species, creating microtopography, and partially filling open water impoundments. The stream buffer and wetland restoration and enhancement areas were planted with bare root trees and shrubs and live stakes in March 2009.

The site will be monitored for at least five years beginning in 2009 through 2013 or until the success criteria are achieved. Reports will be submitted to the EEP each year. The planted riparian buffer and wetland must meet the success criteria of a site average of 320 planted stems/acre at the end of the monitoring period based on the vegetation monitoring plots. The baseline monitoring counted an average of 640 stems/acre in the 15 stream vegetation monitoring plots and 543 stems/acre in the 30 wetland vegetation monitoring plots. The water table of the restored wetlands must be within 12" of the soils surface continuously for at least 5% (12 days) of the 240-day growing season. Wetland hydrology will be monitored with a system of automatic gauges that record water table depth. Stream success will be assessed utilizing measurements of stream dimension, pattern, and profile as well as through site photographs. Two bankfull events also must occur on the restored streams over the monitoring period in separate monitoring years.

1.0 PROJECT BACKGROUND

1.1 Location and Setting

The Farrar Dairy Site occupies portions of nine parcels. The site is located off of Farrar Dairy Road in southern Hartnett County, North Carolina, and approximately is 8.5 miles southwest of Lillington, North Carolina (Figure 1). To reach the site from Raleigh, drive south out of Raleigh on US 401 toward Fuquay-Varina, continuing south from Fuquay-Varina on US-401/US-421 toward Lillington. Turn right onto NC-210 and continue south through Lillington for approximately 6.5 miles to Darroch Road. Turn right onto Darroch Road and continue approximately 3 miles to Powell Farm Road. Turn left onto Powell Farm Road, drive approximately 1.5 miles and the entrance to the site will be on the left through the driveway of the red ranch style home.

1.2 Project Goals and Objectives

The project goals are to:

- Restore the site's riparian buffers and forested wetlands.
- Create a stable stream and wetland complex through an interconnected floodplain corridor.

In order to meet these goals, the following objectives were accomplished:

- Connected the new stream planform to its original floodplain.
- Fill and plug ditches in the drained hydric soils to restore saturated hydrologic conditions to the upper soil horizons.
- Plant a functional Coastal Plain Small Swamp Stream community to create an effective riparian buffer and wetland complex.
- Exclude livestock from the riparian and wetland areas with fencing.

1.3 Project Structure, Restoration Type and Approach

The project streams at the Farrar Dairy Site had become degraded primarily through poor grazing management and vegetation removal. Historically, the mainstem of the NPAC was altered to maximize the use of an agricultural field adjacent to Powell Farm Road. The other significant hydrologic alterations to the site included ditching wetlands and straightening the incoming tributaries to more efficiently convey water through the property. Due to the clearing of the riparian areas, the streams were experiencing significant bank erosion prior to restoration. Severe incision was also occurring on almost all of the reaches. In addition to the ditching that was installed in the historic wetlands, ponds were also built to attract migratory waterfowl. To correct these problems, restoration and enhancement of 13,044 linear feet of channel and 112 acres of wetlands were accomplished utilizing a Priority 1 approach for the stream (Table 1).

1.3.1 Project Streams

The three design reaches of NPAC were restored using a Priority 1 approach, creating a stable C5 channel. The reach breaks are separated by the confluences with T2 and T3. Following the Priority 1 approach, the channel was relocated to its historic location and the bed elevation was brought up reconnecting the stream to the original floodplain. At Station 10+00, the restored channel begins online at the culvert under Powell Farm Road. At Station 21+00, the channel leaves the pre-restoration location and flows through the adjacent forest in the location of its historic channel. The new channel comes back online at the end of the project at Station 76+00.

T1.1 and T1.2 (Station 80+00 to 88+25 and Station 90+00 to 99+80, respectively) were both restored to C5/B5c headwater channels. At the confluence of these two channels, T1 begins. T1 (Station 100+00 to 108+84) was restored using the same approach as T1.1 and T1.2. A 31'-wide easement exception occurs at Station 101+00, where a ford crossing was installed for the landowner. The restoration created a new planform, profile, and dimension and increased the sinuosity of these previously straightened channels with a combination of Priority 1 and 2 approaches. Grade control structures such as log sills and step pools were installed along the new channels to create a stable profile. This restoration created a bankfull bench in entrenched sections and reconnected the stream to the existing floodplain in others.

T2 was divided into two reaches based on the changing slope of the tributary. T2A (Station 110+00 to 115+00) was restored to a C5/B5c stream and T2B (Station 115+00 to 120+22) was restored to an E5 stream type. The hydrologic source for the channel is a seep at the top of T2A. The restoration created a new planform, profile, and dimension and increased the sinuosity of the previously straightened channel with a combination of Priority 1 and 2 approaches. Grade control structures such as log sills and step pools were installed along the new channels to create a stable profile. This restoration created a bankfull bench in some places and reconnected the stream to the existing floodplain in others.

T3 (Station 130+00 to 141+67) is comprised of a single reach that was restored to a C5 channel. This channel was restored using a Priority 1 approach, with a new planform, profile, and dimension being reconnected to the original floodplain. Two drainage ditches that were adjacent to T3 were filled, reestablishing T3 as the primary hydrologic feature in this area.

T4 is separated into two reaches. The first reach (Station 150+00 to 151+80) was enhanced (EII) by planting portions of the easement that had been logged and removing significant amounts of logging debris that had accumulated in the channel, creating unstable conditions. The second reach (Station 151+80 to 164+20) is preservation. Near Station 162+00, the stream flows out of the easement for approximately 100 feet, but then comes back into the easement. The stationing continues from where the stream left the easement.

In-stream structures, including log sills, log drops, riffle grade controls, and offset rock cross vanes, were used to stabilize the restored channels. These structures are designed to reduce bank erosion, influence secondary circulation in the near-bank region of stream bends, provide grade control and promote efficient sediment transport. The log sill and log drop structures enhance in-stream pool habitat by creating a scouring obstruction, maintaining pool depths and providing habitat cover. Coir fiber matting, seeding, and mulching were used to provide temporary stabilization on the newly graded stream banks and live stakes were planted to provide long term rooting strength to the stream banks.

1.3.2 Project Wetlands

Wetland Area 1 preserves approximately 46 acres of well vegetated palustrine forested, scrub-shrub and emergent wetlands that are along the floodplain of the NPAC. The preservation area is dominated by various wetland sedges, rushes and persistent emergent vegetation, but also contains large scrub-shrub alder thickets that are permanently inundated.

Starting from the west and continuing to the east, Wetland Area 2 is located in the general vicinity of Tributary 1. Portions of this area, which is comprised of six wetlands separated by the restored stream, were historically cleared as part of the site's agricultural operations. This area was enhanced through the planting of bare root material. This wetland also borders the restored NPAC, and because NPAC has been reconnected to its floodplain, overbank flooding inundates the adjacent wetlands.

Enhancement in Wetland Area 3 took place in the central portion of the site. The area includes a shallow pond and adjacent overbank areas of the NPAC. Wetland Area 3 is located adjacent to a section of NPAC where overbank flows will have regular access to the floodplain, thus restoring hydrology to the wetlands. This area was planted with wetland trees and shrubs and graded to eliminate the man-made berms that impounded excess surface water.

Wetland Area 4 is located in an area that was heavily manipulated by the landowner to create a series of shallow impoundments intended to attract migratory waterfowl. The impoundments contain water control structures that allowed the landowner to manipulate water levels within the impoundments. These ponds were regraded to create a mosaic of vegetated wet hummocks throughout the wetland. Wetland W4 serves as a transitional area between the ponded features and the wetland preservation area. This area was planted with bare root seedlings and treated to control invasive species.

Wetland Area 5 includes all the site's restored wetlands. These areas are within the floodplain of the NPAC and its tributaries, which had historically been hydrologically altered to allow for agricultural production. Four main construction techniques were utilized to restore these wetland areas:

1. Raising the elevation of the NPAC and its tributaries to re-establish an active floodplain connected to the adjacent wetlands.
2. Filling existing ditches and removing tile drains to discourage rapid groundwater discharge to surface water receptors.
3. Scarifying the top 0.5'of organic surface soil to re-establish soil structure and allow for increased surface storage (microtopography). This material was not removed from the site, but simply re-worked to maximize the ability of the surface soils to retain surface and groundwater hydrology.
4. Planting species of wetland plants and shrubs.

Table 1 below provides a summary of the mitigation actions and units generated from this project.

Table 1. Project Restoration Components
Farrar Dairy Site

Project Streams

Project Segment / Reach ID	Pre- Project Footage	Mitigation Type	Approach	As - Built Footage	As-Built Stationing	Stream Mitigation Units	Comment
NPAC	4,565	Restoration	P1	6,746	10+00-77+46	6,714*	The stream was relocated with a new planform, profile, and dimension.

2.0 PROJECT MONITORING / AS-BUILT CONDITIONS

2.1 Monitoring Features

Permanent monuments, marking monitoring feature locations, were established on-site. The beginning and end of each permanent cross-section was marked with rebar monuments. Vegetation plots were installed with flagged metal conduit at each corner and a flagged PVC pipe was installed at the photo corner. Two automatic recording gauges were installed along the NPAC to record water levels indicating when bankfull events occur. Eight automatic recording gauges were installed in the site's wetlands, seven in the wetland restoration areas and one in the preservation wetland, as a reference, to record hydrology data throughout the growing season. The locations of these monitoring features and the permanent photo points are marked in the As-Built Plan (Appendix A).

2.2 Monitoring Guidelines

Stream data will be calculated from the monitored longitudinal profiles and cross-sections (Tables 5 and 6). Twenty-nine permanent cross-sections were established and will be used to evaluate stream dimension: 12 cross-sections on NPAC, 3 cross-sections each on T1.1, T1.2, T1, and 4 cross-sections each on T2 and T3. Pebble counts will be performed at each cross-section (Appendix B). Cross-sections will be surveyed each year using a total station in order to calculate data such as area and width to depth ratio. A total of over 4,850 linear feet of longitudinal profile will be surveyed. The monitored longitudinal profile will be split into seven representative portions. Two profiles will be taken along the NPAC and will be 1,500 and 600 feet long, while the profiles along T1.1, T1.2, T1, T2, and T3 will be approximately 500 feet each. The profiles will be surveyed with a total station and will record elevations of bed features, water surface levels, and bankfull elevations (Appendix C). Various morphological parameters will be calculated from this information such as bankfull slopes, pool-to-pool spacing, and feature lengths. Stem counts of planted trees and shrubs will be conducted in 15 10 meter x 10 meter vegetation monitoring plots along the stream (Appendix D). These 15 plots will be monitored per the CVS-EEP vegetation monitoring guidelines. Stem counts of planted trees and shrubs will also be conducted in 20 10 meter x 10 meter vegetation monitoring plots in the restored and enhanced wetlands (Appendix D). The stream and wetland gauges on-site will be checked and/or downloaded every other month. The stream gauges will be analyzed to ascertain whether bankfull events have occurred and the wetland gauges will be analyzed to determine if the wetland success criteria is being met. Visual monitoring of the stream, wetland, and riparian buffer will be conducted with annual site walks and site photos will be taken from 30 permanent photo points located throughout the site (Appendix E).

2.3 As-Built Conditions

Baseline stream monitoring data were collected throughout April and May 2009. Any changes made to the design during construction are documented on the As-Built Site Plan in Appendix A. Most of the project was constructed as designed, but field conditions caused small adjustments to be made. Large rain events during construction caused small instabilities in isolated portions of the stream bed and banks. These areas were stabilized with structures, which are indicated on the As-Built Plan.

Table 5 below compares the designed morphological values and ratios to the as-built values and ratios. There are some differences between the design and as-built conditions, but they represent deviations that occurred during construction and not changes from the proposed design. None of these differences should affect the stability of the stream. The table also shows that all of the reaches were restored to streams with a bank height ratio of 1.0 and a stable width to depth ratio.

The wetlands were built as designed. The baseline vegetation data and well installation occurred in April and May of 2009.

*There was no defined pattern for the NPAC due to the stream being channelized.
_The As-built Dimension is from the monitored riffle cross-sections on this reach.
_The As-built Pattern and Profile data is calculated from the monitored longitudinal profile for NPAC which contains parts of both NPAC 1 and 2.

*There was no defined pattern for the NPAC due to the stream being channelized.
_The As-built Dimension is from the monitored riffle cross-sections on this reach.
_While the as-built survey was completed on NPAC-3 and revealed that the stream was built as designed, the monitored detailed longitudinal profile for NPAC does not run through NPAC-3, so no detailed profile data is available for the as-built portion of this table.

Baseline vegetation monitoring data were collected in April 2009. Plot photos from all the vegetation plots can be found in Appendix D.

The results of the baseline monitoring show an average of 640 stems/acre sampled along the stream buffer and 543 stems/acre sampled in the wetland plots (Table 7 and Appendix D). An attempt to identify all trees was made, but since monitoring was conducted while the trees were dormant, many were unidentifiable. All trees will be positively identified during first year monitoring.

Table 7. Planted Stem Density by Plot

3.0 SUCCESS CRITERIA

3.1 Stream Stability

Cross-section measurements should show little or no change from the as-built cross-sections. Annual measurements of the longitudinal profile should indicate a stable bedform with little change from the as-built survey. Sediment transport should remain relatively unchanged with respect to aggradation and deposition of sediments. In sand channels, like the project streams, it is expected that in normal sand channel dynamics large amounts of sand may move through the system as dunes on the stream bottom. These dune features may cause some variations in the monitored cross-sections and profiles, but these will be evaluated to determine whether they are minor adjustments associated with normal sediment transport or whether they indicate movement toward an unstable condition. If any changes occur, they will be discussed within the yearly monitoring reports.

3.2 Vegetation

Stream and wetland vegetation must meet a minimum survival success rate of 320 stems/acre after five years. If monitoring indicates that the specified survival rate is not being met, appropriate corrective actions will be developed, which could include invasive species control, the removal of dead/dying plants, and replanting.

3.3 Hydrology

Within the five-year monitoring period, a minimum of two bankfull events on the restored streams must occur in separate years. If stream gauge data reveal that this criterion is not met, probable causes for this will be determined.

Using criteria from the 1987 Corps Wetland Delineation Manual as a guide, the objective for the wetland restoration site is to establish continuous saturated or inundated hydrologic conditions for at least 12.5 percent of the growing season as defined by NRCS. If soil and vegetation data support a wetland determination, wetland hydrology may also be considered established (as per the 1987 Corps Manual) if well data from the site, or wetland hydrology indicators determine that the water table is within 12 inches of the soil surface for between 5% and 12.5% of the growing season during normal weather conditions. A "normal" year is based on NRCS climatological data for Harnett County, and using the 30^{th} to 70^{th} percentile thresholds as the range of normal, as documented in the USACE Technical Report "Accessing and Using Meterological Data to Evaluate Wetland Hydrology, April 2000." According to the Harnett County Soil Survey, the growing season is considered to extend from March 16 to November 11, yielding 240 days. Therefore, success will be achieved if the water table is within 12 inches of the soil surface for at least 12 consecutive days during the growing season.

4.0 MAINTENANCE AND CONTINGENCY PLAN

The site will be monitored for any problem areas that could arise and any such issues will be dealt with according to severity. Site maintenance may include reinstallation of coir matting, removal of debris from the channel, stabilization of bank erosion with protective structures, or adjustments to in-stream structures. Any maintenance activities will be documented in the yearly monitoring reports.

PLANTING PLAN AND SPECIES COMPOSITION

* UNDISTURBED FORESTED AREAS WITHIN PLANTING ZONES WERE NOT PLANTED

ZONE A

STREAM ZONE = 2.07 ACRES (90,172 SQUARE FEET)
ZONE NOT DISPLAYED ON PLANS. INSTALL LIVE STAKES FROM BOTTOM BANK TO TOP OF BANK ON ALL STREAMS EXCEPT T4.

LIVE STAKES: 1.5' TO 2' LENGTHS, 1/2" TO 2" DIAMETER
3' CENTER SPACING, RANDOM SPECIES PLACEMENT

COMMON NAME	SCIENTIFIC NAME
SILKY DOGWOOD	CORNUS AMOMUM
BLACK WILLOW	SALIX NIGRA
SILKY WILLOW	SALIX SERICEA

NOTE: NO SINGLE LIVE STAKING SPECIES COMPOSED MORE THAN 40% OF THE 11,542 TOTAL NUMBER OF LIVE STAKES INSTALLED

ZONE B1/B2

B1 - STREAM RESTORATION
LOWER RIVERINE PLANTING AREA = 21.13 ACRES

12" - 18" BARE ROOT MATERIAL
436 STEMS/ACRE (10' X 10' SPACING), RANDOM SPECIES PLACEMENT

COMMON NAME	SCIENTIFIC NAME	# OF PLANTS
RIVER BIRCH	BETULA NIGRA	2300
SUGARBERRY	CELTIS LAEVIGATA	904
BUTTONBUSH	CEPHALANTHUS OCCIDENTALIS	1040
SILKY DOGWOOD	CORNUS AMOMUM	1400
GREEN ASH	FRAXINUS PENNSYLVANICA	1900
WATER TUPELO	NYSSA AQUATICA	847
LAUREL OAK	QUERCUS LAURIFOLIA	950
		9241

B2 - STREAM ENHANCEMENT
LOWER RIVERINE PLANTING AREA = 3.67 ACRES

12" - 18" BARE ROOT MATERIAL
100 STEMS/ACRE (10' X 10' SPACING), RANDOM SPECIES PLACEMENT

COMMON NAME	SCIENTIFIC NAME	# OF PLANTS
RIVER BIRCH	BETULA NIGRA	68
SUGARBERRY	CELTIS LAEVIGATA	38
BUTTONBUSH	CEPHALANTHUS OCCIDENTALIS	42
SILKY DOGWOOD	CORNUS AMOMUM	92
GREEN ASH	FRAXINUS PENNSYLVANICA	75
WATER TUPELO	NYSSA AQUATICA	34
LAUREL OAK	QUERCUS LAURIFOLIA	40
		407

ZONE C

UPPER RIVERINE PLANTING AREA = 42.41 ACRES

12" - 18" BARE ROOT MATERIAL
436 STEMS/ACRE (10' X 10' SPACING), RANDOM SPECIES PLACEMENT

COMMON NAME	SCIENTIFIC NAME	# OF PLANTS
SILKY DOGWOOD	CORNUS AMOMUM	908
GREEN ASH	FRAXINUS PENNSYLVANICA	3925
LAUREL OAK	QUERCUS LAURIFOLIA	3110
WATER HICKORY	CARYA AQUATICA	100
SWAMP CHESTNUT OAK	QUERCUS MICHAUXII	4000
CHERRYBARK OAK	QUERCUS PAGODA	2100
PIN OAK	QUERCUS PALUSTRIS	2100
WILLOW OAK	QUERCUS PHELLOS	1900
PERSIMMON	DIOSPYROS VIRGINIANA	300
		18,443

ZONE D

SEASONALLY INUNDATED PALUSTRINE FORESTED WETLAND = 2.95 ACRES

12" - 18" BARE ROOT MATERIAL
436 STEMS/ACRE (10' X 10' SPACING), RANDOM SPECIES PLACEMENT

COMMON NAME	SCIENTIFIC NAME	# OF PLANTS
BUTTONBUSH	CEPHALANTHUS OCCIDENTALIS	216
ATLANTIC WHITE CEDAR	CHAMAECYPARIS THYOIDES	221
