I. Executive Summary

The Third Fork Creek stream restoration project is located in southwest-central Durham, North Carolina, in the headwaters of the Third Fork Creek watershed (US Geological Survey 14-digit Hydrologic Unit Code 03030002060120) within the New Hope Creek Sub-basin of the Upper Cape Fear River (NC Division of Water Quality Sub-basin 03-06-05). The project has restored approximately 2,900 linear feet of perennial stream in the Cape Fear River Basin. Evaluation and design were initiated during the summer of 2002. Construction was completed in January 2005. The stream restoration project's goals were: to restore stable channel morphology, which will reduce bank erosion; improve the watershed's sediment transport; improve aquatic habitat diversity; and increase aesthetic value to local stakeholders.

The preliminary qualitative evaluation was conducted by RJG&A in early February 2006. Subsequent qualitative evaluation was conducted during early March, late June, and September 2006. The second vegetation monitoring data were collected during September 2006, using EEP's August 2006 monitoring protocol. The second annual geomorphologic monitoring data were collected during October 2006.

Overall, the restoration project has met its design goals. Several major geomorphologic changes were documented during the second monitoring year, but overall the site is relatively stable. Aquatic and semi-aquatic organisms have colonized most of the restoration area and the average live planted woody stem density (926 per acre) has exceeded the vegetation restoration goal (320 per acre) by 289 percent.

II. Project Background

A. Location and Setting

The entire restoration site is contained within Forest Hills Park, which is owned by the City of Durham. To get to the Third Fork Creek restoration site from NC 147, take exit 12B and travel south on Roxboro Road. Turn east on West Lakewood Avenue, which merges into University Drive. Forest Hills Park and the Third Fork restoration site are on the left (eastern) side of University Drive (US 15/501 Business, Figure 1). The upstream boundary of the restoration project is immediately downstream from where Third Fork Creek emerges from the box culvert under the northern stretch East Forest Hills Boulevard. The stream restoration extends downstream along the main channel from this point to the southern edge of the Forest Hills Park. The double box culvert under the southern stretch of the East Forest Hills Boulevard loop divides the restoration into upper and lower reaches. An unnamed tributary to Third Fork Creek joins the lower reach on the downstream end of the culvert. The lower reach therefore has a significantly larger watershed.

Forest Hills Park is dominated by lawn/open space with relatively little mature canopy cover (less than 25 percent). A playground and other facilities with impervious cover (e.g. swimming pool, tennis courts, and picnic shelter) are located near the southern portion of the restoration's upper reach. The surrounding area is highly urbanized. The majority of

the land use is dedicated to residential and commercial development and secondary roads. Prior to the restoration, both project reaches were incised and had active bed degradation and channel widening characterized by severe bank erosion.

B. Structure and Objectives

A priority 2 stream restoration approach was used to design and reestablish approximately 3,025 linear feet of meandering, bankfull channel and a new floodplain along Third Fork Creek. The project restored riffle-pool sequencing and used cross-vane and j-hook in-stream structures to provide grade control. The unnamed tributary that enters from the upper reach's left bank (station 20+33) was incorporated and stabilized with a grade control structure to match the grade of the restored channel. Coir fiber matting and live staking were installed/planted to help stabilize the graded stream banks. A 50 foot wide buffer was planted with native species on both sides the restored stream. Space and use needs in the park limited the woody plantings to within 30 feet of the stream. The buffers' outer twenty feet was planted in native grasses and is managed (mowed).

III. Project Conditions and Monitoring Results

RJG&A initially evaluated the site during early February 2006. It was qualitatively evaluated during and after significant storm events in April and May 2006, and during low flow in late June, September, and October. Vegetation monitoring was performed during September 2006, pursuant to the August 2006 EEP guidelines.

Structural failure and compromise were recorded in a number of specific locations. Exotic invasive woody stem density is relatively low. Planted woody stem density is high, as is success. Exotic invasive vines have had a moderate impact on planted woody stem success on several floodplain benches.

In spite of the problem areas the overall restoration project appears to be adequately transporting urban sediment loads and restoring aquatic habitat (i.e. meeting its design functions/goals).

A. Vegetation Assessment

1. Soil Data

Exhibit Table V. Preliminary Soil Data – Third Fork Creek Stream – EEP Project #139 - Durham, NC					
Series	Max Depth (in.)	% Clay on Surface	K	T	OM%
Congaree	80	7-27	0.37	5	0.5-2.0

2. Vegetation Problem Areas

Planted woody vegetation appeared to be successful when qualitatively evaluated during September 2006. Invasive exotic woody species have colonized many locations but are quite sparse, relative to the planted native woody stems. Invasive exotic vines have had a detrimental impact to survival on several floodplain benches that have received overbank flow several times during the 2006 growing season.

Exhibit Table VI. Vegetation Problem Areas – Third Fork Creek Stream – EEP Project #139 – Durham, NC			
Feature/Issue	Station/Range	Probable Cause	Photo #
Exotic Invasive Vines	12+75 – 14+00	Colonization of floodplain by waterborne seeds	VP2&3
Exotic Invasive Woody Stems	12+75 – 14+00	Colonization by air and water borne seeds	VP4&5
Exotic Invasive vines	16+75 – 19+75	Colonization of floodplain by waterborne seeds	VP2&3
Exotic Invasive vines	20+75 – 22+40	Colonization of floodplain by waterborne seeds	VP2&3
Exotic Invasive vines	24+60 – 26+25	Colonization of floodplain by waterborne seeds	VP2&3

Exhibit Table VI. Vegetation Problem Areas – Third Fork Creek Stream – EEP Project #139 – Durham, NC

Disturbed area	29+90 – 30+80	Diseased tree removal by City of Durham maintenance crew	VP1
Woody invasives	34+20 – 35+70	Colonization by air and water borne seeds	VP4&5
Invasive vines	36+60 – 37+25	Colonization of floodplain by waterborne seeds	VP2&3

2.1. Upstream Reach

Planted woody stem success was high in the upstream reach. Japanese hops (*Humulus japonicus*) and porcelainberry (*Ampelopsis brevipedunculata*) have densely colonized the floodplain benches inside several meanders. In addition to directly competing for light with the planted woody species, these exotic invasive woody vines have caused many of the planted woody stems in these areas to be severely impacted by storm flow. Once rooted, most woody stems can withstand moderate flood events (i.e. they are bent during over-bank flow, but not uprooted. With a dense layer of woody vine stems wrapped around and through them, many planted individuals are uprooted, overturned, and washed away entirely. Manual removal of these vines could be an effective management practice, if it is done regularly. If not, the vines will recolonize the floodplain benches from existing root stock, or from the large monocultures of these species upstream (on/over both banks throughout the American Tobacco Trail right-of-way (~1,400 feet upstream)).

2.2. Downstream Reach

The downstream reach also has invasive exotic woody vines inside one meander and some exotic invasive woody species along a portion of one bank.

3. Stem Counts

Eight representative vegetation survey plots were selected and installed in the upstream and downstream reaches during September 2006, pursuant to the new EEP vegetation monitoring protocol (August, 2006). Where appropriate, the new monitoring plots were co-located with the first year monitoring plots. Pursuant to the August 2006 protocol, all plots measure 100 square meters in area and are either 10 meters by 10 meters, or five meters by 20 meters. Level 1 (planted woody stems) and Level 2 (volunteer woody stems) data collection was performed concurrently with plot selection, during September 2006. Because the new plot dimensions are different than the first annual vegetation monitoring plots, direct comparison with the first year data is inappropriate.

Pursuant to the new guidelines, the four corners of each plot (e.g. 0,0; 0,10; 10,0; and 10,10; or 0,0; 0,20; 5,0; and 5,20.) were marked with 18 inch long one half inch diameter galvanized steel conduit. Within each plot, each planted woody stem location (x and y) was recorded and live stem diameter at decimeter height (ddm), and height (cm) were recorded.

The average live, planted woody stem density for all plots was 22.88 individuals per plot, which translates to 929.95 stems per acre. This exceeds the required 320 stems per acre by 291 percent.

4. Vegetation Plot Photos

Vegetation plot photos are in Appendix A.

B. Stream Assessment

RJG&A personnel initially evaluated the site during early February 2006. It was qualitatively evaluated during and after significant storm events in April and May 2006, and during low flow in late June, September, and October 2006. The second annual cross section, pattern, and longitudinal profile data were collected during October 2006.

Markers for cross sections one and two were not re-located in the field, using a total station and a metal detector. Their locations were established using total station survey equipment and best professional judgment. While not in the identical location as the monitoring year 01 and as-built cross sections, the Year 02 cross section locations are within 20 feet, likely upstream. Because these locations provide representative stability condition data very close to the year 1 and as-built, their comparison to the original data is appropriate. Photographs were taken at the four cross sections and at the 14 permanent photo locations that were established by KCI in March 2005.

Overall, the site is maintaining its as-built dimension, pattern, and profile, and planted woody stem success is high. Several stretches of bank erosion are present in both reaches. One of these (station 34+27) is fairly significant, and getting worse (i.e. it has expanded laterally and longitudinally since February). Remedial action (e.g. armoring with root wads and/or rock) should be considered. Overall, the remaining bank slumps and undercuts are relatively minor and should continue to be monitored, as they may equilibrate themselves over time. The only other significant problem area (i.e. remedial action should be considered) is a backcut j-hook that has had its upstream-most header rock undercut (station 27+04). The rock has been completely dislodged and fallen back (upstream) into the scoured channel. The remaining j-hook/cross vane problem areas are relatively minor and should continue to be observed, to determine if remedial action should occur.

A *wetted perimeter* bed material analysis was performed at each cross section during October 2006. The difference between the second annual monitoring substrate analysis and the first year's indicates that the upstream-most channel bed has become finer (xs1), while the downstream-most bed (xs2-4) have become coarser. The most significant change was observed at cross section 3.

On-site evidence of over-bank flow (26 June 2007)

Two pressure transducers were observed during the initial evaluation in February. The serial numbers, brands and model numbers were recorded. A Solinst Levelogger 3001 reader was subsequently purchased and installed into a laptop. The laptop was brought to the site on 25 April 2006. The gauges had been removed from the PVC crest gauge pipes that held them. Neither gauge was found, after an extensive search, including inside the installed pipe. The upstream unit still had

its lock, the lower one had a broken top (above photo). **The units are presumed to have been removed by vandals.** On-site hydrologic data are therefore not available for the second annual monitoring. Qualitative evaluation (rake and drift lines and downed herbaceous and woody vegetation on the floodplain) indicated at least three events during 2006 (April, June, and September (above photo)).

Potential bankfull events were also evaluated based on USGS stream gauge discharge data for Ellerbe Creek near Gorman (USGS 02086849). This gauge is located approximately 8 miles northeast of the restoration site and has a drainage area of 21.9 square miles. According to the urban piedmont regional curve, a stream with a drainage area of 21.9 square miles would reach a bankfull discharge at 2,144.5 cubic feet per second (cfs) (Doll et al., 2002). Based on USGS data for 2006 (Figure 3), there have been no bankfull events at this gauge. The highest flow event during 2006 was 1080 cfs on November 22th, which is less than half of the bankfull discharge predicted by the urban piedmont regional curve. Using the rural piedmont regional curve, bankfull discharge is 819.7 cfs, making the high flow event on November 22nd the only bankfull event of the year.

The 2006 qualitative evaluation of Third Fork Creek clearly indicates that at least one, probably three storm events resulted in flows over the designed/built bankfull elevation.

*No as-built numbers were provided. The Third Fork mitigation plan (December 2005)

and the First Year Monitoring Report (December 2005) both provide Design numbers only, therefore the design numbers have been provided in the as-built columns, but are redundant of those figures appearing earlier in the table.

Third Fork Creek Stream Restoration

2006 Monitoring Report

EEP Project #139

Year 2 of 5

C. Wetland Assessment

No wetland restoration was included in this project.

Third Fork Creek Stream Restoration – Durham County, NC
