EXECUTIVE SUMMARY

The Harrell Stream and Wetland Restoration Site is a full-delivery project that was developed for the North Carolina Ecosystem Enhancement Program (EEP). Construction was completed in September 2007 on an Unnamed Tributary to Swift Creek and 15.0 acres of Coastal Plain Small Stream Swamp wetland community. The 441-acre watershed at the downstream limits of the project stream and the 57-acre watershed draining into the project wetland are located within the USGS 14-digit HUC 03020101130090 and the NCDWQ Sub-basin 03-03-02 in the Tar-Pamlico River Basin. The project restored 6,808 linear feet of channel using a combination of Priority 2 and 3 approaches, and 15.0 acres of Coastal Plain Small Stream Swamp wetland community, generating 6,808 stream mitigation units and 15.0 wetland mitigation units. The stream design addressed vertical instability problems and a lack of bed variability by stabilizing stream banks, installing in-stream structures, adjusting stream planform, and replanting the riparian areas with native vegetation. The wetland was restored by filling ditches, creating microtopography, and planting native trees and shrubs. This report describes the results from the findings of the first year of monitoring that took place in 2008.

The riparian buffer was planted with twelve different species of bare root trees and shrubs and three different species of live stakes. The restored wetland was planted with eleven different species of bare root trees and shrubs. Vegetation monitoring plots were established during the as-built survey and included 18 monitoring plots placed throughout the stream buffer and 12 monitoring plots installed in the restored wetland. Vegetation must meet a minimum survival success rate of 320 stems/acre after five years. These plots were monitored during the first-year monitoring period. The first-year monitoring counted an average of 607 stems/acre in the stream plots and 533 stems/acre in the wetland plots. The first-year monitoring found the vegetation component of the project to be on track to meeting the success criteria.

The stream assessment completed during first-year monitoring found the stream to be stable and functioning properly. Channel dimensions have not changed significantly from the as-built conditions over the course of the growing season. Small portions of localized bed erosion and aggradation have been noted during the first-year monitoring. These areas have been documented in the Current Conditions Plan View. The on-site stream gauges have recorded 3 bankfull events since the project was constructed in September 2007.

During the 2008 monitoring year, wetland hydrology was achieved at all four wells in the restoration area. Groundwater was within 12 inches of the soil surface in excess of 12 consecutive days (5% of the growing season) at each well, with two of the gauges having groundwater within 12 inches of the soil surface for more than 12.5% of the growing season.

The daily rainfall data depicted on the gauge data graphs were obtained from the on-site precipitation gauge. The precipitation gauge was installed on the site prior to project implementation. The daily rainfall data obtained from a local weather station shows that the area had below average rainfall during the growing season in 2008 and correlated to the precipitation data recorded on-site.

1.0 PROJECT BACKGROUND

Project Goals and Objectives

The goals and objectives of the restoration project are as follows:

Restoration Goals:

- Protect aquatic resources from excess nutrients, sediment, and other pollutants coming from the agricultural watershed.
- Reestablish terrestrial and aquatic habitat and connect the site to the existing floodplain corridor along Swift Creek.

Restoration Objectives:

- Restore 6,808 linear feet of stable stream channel with the appropriate pattern, profile, and dimension that can support a sand transport system.
- Connect the stream to a functioning floodplain.
- Fill and plug ditches in the drained hydric soils to restore saturated hydrologic conditions for 5% of the growing season.
- Plant tree species typical of a Coastal Plain Small Swamp Stream along the stream riparian corridor and floodplain as well as in the restored wetland.

1.1 Project Structure, Restoration Type, and Approach

Prior to restoration, UT to Swift Creek had been channelized and straightened since at least 1948. The entire site, including where the wetland was restored, was under agricultural production. There were fields adjacent to the stream and the wetland that had been drained by a network of ditches. There were no remaining vegetated buffers or instream features in the channel and the banks were nearly vertical. The channel was characterized as having poor streambed variability and habitat diversity. Restoration of 6,808 linear feet of channel was accomplished utilizing a combination of Priority Levels 2 and 3 (Table 1). Reach 1 (Station 10+00 to 22+26) was restored using a Priority Level 3 approach. The restoration of a B5c channel with a sinuosity of 1.06 was accomplished by building a bankfull channel with a higher width/depth ratio than the existing stream, creating distinct bed features by adding pools and riffles to the profile, and grading back the upper slopes to create an appropriate valley for the stream. Reaches 2, 3, and 4 (Stations 22+26 to 36+91, 36+91 to 51+82, and 51+82 to 78+80, respectively) were restored to a C5 channel with a Priority Level 2 restoration. The restoration established a bankfull channel with a new floodplain where the designed bankfull stage equals the new floodplain elevation (bank height ratio=1.0). Reaches 2, 3, and 4 have sinuosity values of 1.07, 1.23, and 1.10, respectively. The four different reaches are shown in Figure 2.

1.2 Location and Setting

The Harrell Stream and Wetland Restoration Site is located approximately six miles northeast of Rocky Mount, North Carolina in Edgecombe County (Figure 1). The latitude and longitude of the project site are 36.0201 North and 77.6807 West (WGS1984). To reach the site from Raleigh, proceed east on U.S. Route 264-East/64-East (US 264E/64E) for approximately 17 miles. Continue on US 64E for another 30 miles. Take the U.S. Route 301 Bypass and then U.S. Route 301 (US 301) north into Battleboro. Make a right onto Battleboro-Leggett Road and then turn left onto Morning Star Church Road just outside of town. Proceed through Cherry Crossroads and continue for 2.25 miles. The project site is on the left side of Morning Star Church Road and is directly opposite the junction with Benson Farm Road.

2.0 PROJECT CONDITIONS AND MONITORING RESULTS

2.1 Vegetation Assessment

The planted vegetation on the site is growing well. Due to the baseline vegetation monitoring occurring while the plants were in dormancy, some of the plants could not be identified and their species was recorded as unknown. During the first year of monitoring, most of these plants were identified. Some of the previously unknown plants were dead, damaged, or missing and could not be identified during the first year monitoring. These plants were again recorded as unknown.

The low stream flow throughout the summer months allowed vegetation to become established in the stream channel. This vegetation included grasses, rushes, cattails, and Asian dayflower (*Murdannia keisak*). While contributing to the overall stream stability, this vegetation could contribute to aggradation in the channel by trapping sediment. Further monitoring will determine if channel vegetation becomes a problem.

The floodplain, stream banks, and riparian buffer have small areas of sparse vegetation, but overall they are well vegetated. Some scattered populations of invasive species have been identified in the floodplain area, which include: Chinese lespedeza (*Lespedeza cuneata*) and tropical soda apple (*Solanum viarum*). Asian dayflower was present within the channel in isolated areas. Japanese honeysuckle (*Lonicera japonica*) was observed on the outer edges of the project. Although they are not a problem at this time, these populations will continue to be monitored to determine if invasive control is required in the future.

The monitored vegetation plots within the stream buffer and wetland revealed that the planted vegetation is growing well with 607 and 533 stems/acre, respectively. The overall vegetation assessment found the site to be on track to meeting the vegetative success criteria.

The vegetative monitoring results are displayed in Appendix A and the Current Conditions Plan View in Appendix C.

2.2 Stream Assessment

During the 2008 growing season, the stream experienced low flow throughout the summer. This flow allowed vegetation to become established in some areas of the stream. The vegetation has not caused any problematic aggradation at this time, but it will continue to be monitored. The on-site stream gauge recorded a bankfull event on July 6, 2008.

The stream assessment found the stream to be generally stable. Periodic storm events caused isolated bed degradation and aggradation in reaches 1 and 2. Some of these areas are visible on the longitudinal profile and cross-section plots. These patterns are typical for a stream like UT to Swift Creek. A sand bed system, like the project stream, is much more mobile than a gravel stream. Because of this, it is expected that patterns of aggradation and degradation are more dynamic within these systems. These dune/anti-dune streams will experience bed variation over time. The stream banks and floodplain experienced little to no erosion throughout the project. Piping is occurring at one instream structure, but the rest of the structures are performing as designed. Water quality treatment areas are stable and retaining water. All of these stream features will continue to be monitored to make sure that any observed changes are within the range of variability found in stable stream systems.

The stream assessment monitoring is described in Appendix B and the Current Conditions Plan View in Appendix C.

2.3 Wetland Assessment

The maximum number of consecutive days that the groundwater was within 12 inches of the surface was determined for each groundwater gauge. This number was converted into a percentage of the 223-day growing season. Table 5 presents the hydrological monitoring results for 2008. The wetland wells used to monitor site hydrology were installed in the spring of 2007. During the first year of monitoring wetland hydrology was achieved at all of the wells on the site (Table 5). Based on these data, the site has exceeded the minimum duration of 12 consecutive days with the water table within 12 inches of the soil surface for the 2008 growing season (Appendix B). Climatic data for the 2008 growing season were analyzed in comparison to historical data to determine whether 2008 was a normal year in terms of climatic conditions. The historical data were collected from the NRCS, Water and Climate Center, "Climate Analysis for Wetlands by County" website. This evaluation concluded that 2008 was a below normal year for rainfall during the growing season. Rainfall was within the 30th to 70th percentiles for the months of July, August, September and November. Rainfall was less than the 30th percentile threshold in March, May, June and October and was greater than the 70th percentile threshold in April (Appendix B).

2.3.1 Wetland Criteria Attainment Tables

Table VIIIa. Hydrologic Monitoring Results

Project Name: Harrell Stream and Wetland Restoration

Well #	Hydroperiod					Dates Meeting Success
	<5%	5% - 8%	8% - 12.5%	>12.5%	Max. No. of Consecutive Days	
1		X			16	4/4/08-4/19/08
2				X	38.5	3/29/08-4/24/08
3		X			16	4/20/08-5/6/08
4				X	32	4/4/08-5/5/08

Table VIIIb. Hydroperiod History

Harrell Stream and Wetland Restoration

Well #	Pre-Restoration	Year 1	Year 2	Year 3	Year 4	Year 5
1	<5%	5%-8%				
2	<5%	>12.5%				
3	<5%	5%-8%				
4	<5%	>12.5				

3.0 SUCCESS CRITERIA

The stream is functioning as designed and has not developed any significant problems. The changes that are visible in the monitored cross-sections and profiles indicate adjustment of the stream due to its sand bed. Any feature changes will be tracked to see if the stream is moving beyond its expected variability. With three bankfull events since construction, the stream is on track to meeting the success criteria

The hydrology data in Section 2.3 indicates that the wetland is on track to meeting the success criteria.

The planted vegetation has been doing well, with some plots experiencing more mortality than others. This mortality can be attributed to normal losses after the initial planting as well as to the effects of last year's exceptional drought. Some invasive species have been identified on the site, which include Chinese lespedeza (*Lespedeza cuneata*), Japanese honeysuckle (*Lonicera japonica*), tropical soda apple (*Solanum viarum*) and Asian dayflower (*Murdannia keisak*). The exotic vegetation is not widespread across the project, but these populations will continue to be monitored to determine if control measures will be required in the future. The vegetation is on track to meeting the success criteria in the steam and wetland for the first year of monitoring.

4.0 MAINTENANCE

Maintenance was performed along the restored stream near stations 23+00, 37+00, 39+60 and 52+75. Minor bank and bed stabilization was conducted with rock at station 23+00 due to bed degradation. Near station 37+00 the banks of an incoming drainage ditch within the easement were sloped back and stabilized to alleviate bank erosion from the ditch. To further facilitate floodplain drainage, rock stabilization was added near Stations 39+60 and 52+75 where erosion was occurring as field drainage entered the channel. At each station erosion had been occurring. If any further maintenance actions are warranted, they will be documented in future monitoring reports.
