1.0 PROJECT GOALS AND OBJECTIVES

The project goals of the Hudson property per the approved mitigation plan are as follows:

- Improve and sustain hydrologic connectivity/interaction and storm flow/flood attenuation.
- Reduce nutrient and sediment stressors to the reach and receiving watershed.
- Provide uplift in water quality functions.
- Improve aquatic and terrestrial habitats (complexity, quality).
- Improve and maintain riparian buffer habitat.

The project goals will be addressed through the following project objectives:

- Implement a sustainable, reference-based, rehabilitation of the reach dimension, pattern, and profile to provide needed capacity and competency.
- Support the removal of barriers to anadromous fish movement and to help improve nursery and spawning habitats.
- Strategically install stream structures and plantings designed to maintain vertical and lateral stability and improve habitat diversity/complexity.
- Provide a sustainable and functional bankfull floodplain feature.
- Enhance and maintain hydrologic connection between stream and adjacent floodplain/riparian corridors.
- Utilize the additional width of the swamp runs to provide natural filters for sediment and nutrients and diffuse flow from upstream runoff.
- Install, augment, and maintain appropriate riparian buffer with sufficient density and robustness to support native forest succession.
- Water quality enhancement through riparian forest planting and woody material installation, and increased floodplain interaction/overbank flooding.
- Restore the existing ditched streams to single and multi-thread headwater systems with forested riparian buffers.
- Provide ecologically sound construction techniques that will require minimal grading and disturbance.

2.0 PROJECT SUCCESS CRITERIA

2.1 Stream Restoration Performance Standards

Single Thread Channels (Reaches 1 - 4) and Swamp Run (Reach 5)

Groundwater monitoring wells are installed in and near the thalweg of all five reaches. The wells are equipped with continuous-reading gauges capable of documenting sustained flow. Per the approved Mitigation Plan, each reach must exhibit water flow for at least 30 consecutive days during years with normal rainfall (demonstrating at least intermittent stream status). All restored channels shall receive sufficient flow through the monitoring period to maintain an Ordinary High Water Mark (OHWM). Field indicators of flow events include a

natural line impressed on the bank; shelving; changes in soil characteristics; destruction of terrestrial vegetation; presence of litter and debris; wracking; vegetation matted down, bent or absent; sediment sorting; leaf litter disturbed or washed away; scour; deposition; bed and bank formation; water staining; or change in plant community. In addition, two overbank flows shall be documented for each reach during the monitoring period using continuously monitored pressure transducers and crest gauges. All collected data and field indicators of water flow shall be documented in each monitoring report. Seven flow monitoring stations are located on Reaches 1 – 4, three are located in Reach 5.

2.2 Stream Channel Restoration Stability Performance Standards

Headwater System (Reach 5)

All stream areas shall remain stable with no areas of excessive erosion such as evidence of bank sloughing or actively eroding banks due to the exceedance in critical bank height and lack of deep rooted stream bank vegetation.

Single Thread Channels (Reaches 1 - 4)

1. Bank Height Ratio (BHR) shall not exceed 1.2 within restored reaches of the stream channel.
2. Entrenchment Ratio (ER) shall be no less than 2.2 within restored reaches of the stream channel.
3. The stream project shall remain stable and all other performance standards shall be met through two separate bankfull events, occurring in separate years, during the 7-year post construction monitoring period.
4. Three bank pin arrays and 11 cross sections are located on Reaches 1 - 4

2.3 Planted Vegetation Performance Standards

1. At least 320 three year-old planted stems/acre must be present after year three. At year five, density must be no less than 260 five year-old planted stems/acre. At year 7, density must be no less than 210 seven year-old planted stems/acre.
2. If this performance standard is met by year 5 and stem density is trending toward success (i.e., no less than 260 five year-old stems/acre) monitoring of vegetation on the site may be terminated provided written approval is provided by the USACE in consultation with the North Carolina Interagency Review Team (NCIRT).
3. Thirteen vegetation plot samples are located within the project area.

3.0 SITE CONDITIONS AND DESCRIPTION

The Hudson property is 13.49 acres located in Beaufort County, NC and the Tar-Pamlico River Basin. The majority of the site is used for crop production, primarily corn, soybeans and wheat. As a result of the lowering of local water tables and in some cases the complete elimination of ground and surface water interaction, the degradation of water quality and downstream anadromous fish spawning and nursery habitat has occurred. Hydric soils are present on site, meaning that the pre-existing site conditions

were appropriate for raising the water table and re-establishing normal base flow conditions (See Figure 1 -Vicinity Map).

4.0 MITIGATION COMPONENTS

Mitigation components are limited to five reaches: Reach 1: 833 lf; Reach 2: 532 lf; Reach 3: 445 lf; Reach 4: 437 lf; Reach 5: 644 lf, for a total restored stream footage of 2,891 linear feet (Table 1).

5.0 DESIGN APPROACH

A natural design approach was used to restore the natural sinuosity and flow of the headwater streams which existed prior to channelization. Grading was done to decrease sediment load and erosion rate while allowing for floodplain connectivity and storage for overland flow. Banks were graded down to distribute flow velocity and the banks and riparian buffers were planted to stabilize the channel and create habitat. A combination of Priority 1 and Priority II restoration types were used. Where the proposed channels tie into the existing, non-restored channels, Priority II restoration was used.

6.0 CONSTRUCTION AND PLANTING TIMELINE

Construction commenced in December 2014 with the installation of recommended erosion control practices and was completed in May 2015. Planting was officially concluded in early January 2016. (Table 2 – Project History Table)

The construction sequence was as follows:

1. Conduct channel grading to raise channel elevation and reconnect floodplain.
2. Install in-stream structure (riffle grade control structure with embedded woody branches, low gradient log drop structures, and soil lifts) in accordance with approved restoration plans (Sheets D14-15).
3. Install soils stabilization matting and E & S seeding along all graded.
4. Seed stream restoration reaches with the permanent wetland seed mixture as specified in the restoration plans (Sheet P-1).
5. Install live stakes where specified on the approved stream restoration plans.
6. As-built and baseline monitoring surveys were completed. Nine monitoring wells were installed along with 13 vegetative monitoring plots (minimum of .02 acres in size).
7. Tree planting was completed in January 2016. All planting was done in accordance with the approved restoration plan.

7.0 PLAN DEVIATIONS

There were no significant deviations between construction plans and the As-built conditions.

8.0 POST-CONSTRUCTION MITIGATING FACTORS

Due to abnormally high amounts of rainfall during the winter of 2014-15, all restoration activities were suspended from December 14, 2014 through March 23, 2015. This caused changes to the construction sequence and set back reforestation activities. Refer to Table 2 for the actual timeline.

Hudson Stream Restoration Project – Baseline Report FINAL
 August 2016 DMS Project # 95361

Pattern data will not typically be collected unless visual data, dimensional data or profile data indicate significant shifts from baseline

Appendix E: As-built Plan Sheets
