1.0 PROJECT SUMMARY

1.1. Goals

The project goals address stressors identified in the Targeted Local Watershed (TLW) and include the following:

- Improve water quality within the restored channel reaches and downstream watercourses through:
 - reducing turbidity by stabilizing existing stream banks and altering stream channel dimension, pattern and profile
 - reducing nutrient loads and fecal coliform bacteria from adjacent agricultural fields by fencing the riparian area to keep livestock out of the stream and restoring a wooded riparian buffer
- Improve local aquatic and terrestrial habitat and diversity within the restored channels and their vicinity through:
 - reducing water temperatures by planting native vegetation in the riparian zone and creating shade
 - improving habitat complexity by restoring the stream profile to stable riffle/pool complex and step/pool complexes
 - improving terrestrial habitat by excluding livestock and creating a riparian buffer comprised of native plant species
 - improving aquatic habitat by establishing tree canopy to provide organic material such as woody debris and leaf packs to stream
 - removing invasive exotic species and planting native vegetation in the riparian buffer
- Improve flood flow attenuation on-site and downstream through:
 - raising the bed or creating bankfull benches to allow for overbank flows every 1-2 years and improve the connection to the active floodplain

1.2. Success Criteria

1.2.1. Morphological Parameters and Channel Stability

Restored and enhanced streams shall be in compliance with the standards set forth in the USACE 2003 Stream Mitigation Guidelines and should demonstrate morphologic stability to be considered successful. Stability does not equate to an absence of change, but rather to sustainable rates of change or stable patterns of variation. Restored streams often demonstrate some level of initial adjustment in the several months that follow construction and some change/variation subsequent to that is also to be expected. However, the observed change should not be unidirectional such that it represents a robust trend. If some trend is evident, it should be very modest or indicate migration to a stable form.

Dimension - Cross-section measurements should indicate little change from the as-built cross-sections. If changes do occur, they will be evaluated to determine whether the adjustments are associated with increased stability or whether they indicate movement towards an unstable condition.

Pattern and Profile - Measurements and calculated values should indicate stability with little deviation from as-built conditions and established morphological ranges for the restored stream type. Pool depths may vary from year to year, but the majority should maintain depths sufficient to be observed as distinct features in the profile. The pools should maintain their depth with flatter water surface slopes, while the riffles should remain shallower and steeper. Pattern measurements will not be collected unless conditions seem to indicate that a detectable change appears to have occurred based on profile and/or dimension measurements.

Substrate - Calculated D₅₀ and D₈₄ values should indicate coarser size class distribution of bed materials in riffles and finer size class distribution in pools. The majority of riffle pebble counts should indicate maintenance or coarsening of substrate distributions. Generally, it is anticipated that the bed material will coarsen over time.

Sediment Transport - Depositional features should be consistent with a stable stream that is effectively managing its sediment load. Point bar and inner berm features, if present, should develop without excessive encroachment of the channel. Isolated development of robust (i.e. comprised of coarse material and/or vegetation actively diverting flow) mid-channel or lateral bars will be acceptable. Likewise, development of a higher number of mid-channel or lateral bars that are minor in terms of their permanency such that profile measurements do not indicate systemic aggradation will be acceptable, but trends in the development of robust mid-channel or alternating bar features will be considered a destabilizing condition and may require intervention or have success implications.

Surface Water Hydrology - Monitoring of stream surface water stages should indicate recurrence of bankfull flow on average every 1 to 2 years. At a minimum, throughout the monitoring period, the surface water stage should achieve bankfull or greater elevations at least twice. The bankfull events must occur during separate monitoring years.

1.2.2. Vegetation

Riparian vegetation monitoring shall be conducted for a minimum of five years to ensure that success criteria are met per USACE (2003) guidelines. Accordingly, success criteria will consist of a minimum survival of 320 stems per acre by the end of the Year 3 monitoring period and a minimum of 260 stems per acre at the end of Year 5. If monitoring indicates either that the specified survival rate is not being met or the development of detrimental conditions (i.e., invasive species, diseased vegetation), appropriate corrective actions will be developed and implemented.

1.3. Project Setting and Background

The Junes Branch Restoration Site (Site) is located in central Jackson County approximately 2 miles east of Sylva, NC (Figure 1). The site encompasses 5.8 acres of formerly agricultural land and includes portions of Bumgarner Branch and three unnamed tributaries that, for purposes of the project, are referred to as Junes Branch, Higdon Branch, and Doris Branch. The site is located within the Little Tennessee River Basin, United States Geological Survey (USGS) 14-digit Hydrologic Unit 06010203020010, and the North Carolina Division of Environmental Quality (NCDEQ) sub basin 04-04-02. The site watershed is characteristic of the Blue Ridge region with moderate rainfall with annual precipitation averaging 52.9 inches. Elevation within the site ranges from 2,200 feet at the northwestern extent, to 2,150 feet along Junes Branch. The drainage area of Bumgarner Branch at the downstream end of the Site is 1.03 square miles (668 acres). Land use within the watershed is predominately forested (68%) with the remaining land use composed of low-density residential (21%) and agricultural (11%). Additional information regarding project setting and background is found in the Final Mitigation Plan (EBX 2013).

1.4. Project Approach

Channel restoration involving improved pattern, dimension, and longitudinal profile was completed on all four stream reaches. A Priority I approach was applied to all four reaches of the project (Rosgen 1996; NCSRI 2004).

1.5. Project Performance

Monitoring Year 2 (MY2) data was collected from July through November 2015. Monitoring included the following activities: visual assessment of all reaches and the surrounding easement, collection of photos at fourteen permanent photo stations, documentation of vegetation at five permanent monitoring plots, surveying of 3,050 feet of longitudinal profile, fifteen cross-sections, and conducting pebble counts at eight riffles.

Generally, visual assessment of the project as a whole indicates that the streams are performing as desired and, with the exception of two small bare areas, vegetation is well established throughout the easement. Summary tables and photos taken at the permanent photo stations associated with the visual assessment are presented in Appendix B. Visual assessment of the stream was performed to document signs of instability, such as eroding banks, in-stream structural instability, or excessive sedimentation. No indication of instability was observed (Table 5 and Figure 2). Structures are intact and performing as designed. Herbaceous vegetation has become well established in both the wetland fringes along the stream as well as upland areas. Planted stems are becoming well established; however, two bare areas totaling 0.07 acre were noted along the Junes Branch reach (Table 6, Figure 2). The one small area of encroachment (mowing) noted at the private driveway crossing during MY1 has been corrected and vegetation is becoming re-established.

Monitoring of permanent vegetation monitoring plots ($n = 5$) was completed during September 2015. Summary tables and photographs associated with MY2 monitoring can be found in Appendix C. Vegetation data for MY2 indicate that all vegetation monitoring plots are on track to meet the MY3 interim success criteria of 320 stems per acre. Stem densities ranged from 364 to 688 stems per acre with a mean of 526 stems per acre across all plots. A total of 12 species were documented within the monitoring plots. When volunteer stems are included, densities ranged between 728 and 2,064 stems per acre with a mean of 1,392 stems per acre across all plots.

Geomorphic data for MY2 was collected from October through November 2015. Summary tables, cross-section plots, and longitudinal profiles related to stream morphology are located in Appendix D. Changes in the cross-section data between MY1 and MY2 were limited to Cross-Sections 3 and 13 (Appendix B, Table 11a). Riffle cross-section 3, where downcutting of the channel was evident in MY1 has begun to stabilize, however the max depth still increased by 0.2 feet from MY1 to MY2. Deposits of finer material in pools led to a decrease of 0.1 feet to 0.6 feet in maximum pool depth in cross-section 13.

Generally, longitudinal profile data (Appendix B, Table 11b) indicated relatively little change in riffle and pool dimensions between MY1 and MY2. All reaches showed a decrease in riffle length of between 0.2 feet and 1.6 feet, however these numbers are now falling closer to the baseline conditions. Each reach, with the exception of Doris Branch, also showed a decrease in average maximum pool depth between 0.1 feet and 0.2 feet.

Substrate monitoring was also performed during MY2. Riffle D_{50} has decreased between MY1 and MY2. The average D_{50} fell into the coarse sand size class for Bumgarner I, fine gravel for Bumgarner II, medium sand for Junes Branch, fine sand for Higdon Branch, and silt to fine sand for Doris Branch. The shift towards finer particle size classes throughout the project is likely due to fine sediment being transported into the project area from upstream and dropping out of the water column during the falling limb of high flow events. Additionally, the dense herbaceous vegetation throughout all reaches increases entrapment of fine material during high flows. As woody vegetation continues to establish, herbaceous vegetation density in and near the channel will decrease, allowing more efficient transport of finer particle size classes during high flows. A gravel and cobble layer is still present under a layer of finer silts and

sand at all riffles assessed during pebble counts. Substrate will be monitored in future years for shifts in size composition.

Overall, documented shifts in stream morphology do not exceed expectations between MY1 and MY2 as the constructed stream adjusts to conditions at the site. The project is meeting success criteria regarding stable dimension, pattern, and profile as well as substrate and sediment transport.

A bankfull event was recorded on the crest gauge at Bumgarner Branch II on a July site visit, at 0.1 feet above the bankfull elevation (Appendix E, Table 12).

Summary information/data related to the occurrence of items such as beaver or encroachment and statistics related to performance of various project and monitoring elements can be found in the tables and figures in the report appendices. Narrative background and supporting information formerly found in these reports can be found in the Baseline Monitoring Report (formerly Mitigation Plan) and in the Mitigation Plan (formerly Restoration Plan) documents available on DMS's website. All raw data supporting the tables and figures in the appendices is available from DMS upon request.

2.0 METHODS

Visual assessment of the stream was performed at the beginning of the monitoring period. Permanent photo station photos were collected during the initial visual assessment. Vegetation or stream problem areas occurring outside of the monitoring stations were documented with additional photographs.

Geomorphic measurements were taken during low flow conditions using a Nikon® NPR 332 Total Station. Three-dimensional coordinates associated with cross-section and profile data were collected in the field and geo-referenced (NAD83 State Plane feet FIPS 3200). Morphological data was limited to 15 cross-sections, and 3,050 feet of longitudinal profile. Survey data was imported into CAD, ArcGIS®, and Microsoft Excel® for data processing and analysis. Channel substrate was characterized using a Wolman Pebble Count outlined in the Harrelson et al (1994) and processed using Microsoft Excel.

Vegetation success is being monitored at 5 permanent monitoring plots. Vegetation monitoring follows the CVS-EEP Level 2 Protocol for Recording Vegetation, Version 4.2 (Lee et al. 2008) and includes analysis of composition and density of planted species. Data is processed using the CVS data entry tool. In the field, the four corners of each plot were permanently marked with rebar and photos of each plot are taken from the origin each monitoring year.

Precipitation data was collected using an Onset® HOBO® Data Logging Rain Gauge. Bankfull events were documented with crest gauges. During quarterly visits to the site, the height of the corkline was recorded and cross-referenced with known bankfull elevations at each crest gauge.

Report Prepared By	Drew Alderman
Date Prepared	9/11/2015 13:23
database name	Equinox_2015_A_Junes.mdb
database location	Z:\ES\NRI&M\EBX Monitoring\Junes\MY2-2015\Data\Veg
computer name	FIELD-PC
file size	61181952
DESCRIPTION OF WORKSHEETS IN THIS DOCUMENT	
Metadata	Description of database file, the report worksheets, and a summary of project(s) and project data.
Proj, planted	Each project is listed with its PLANTED stems per acre, for each year. This excludes live stakes.
Proj, total stems	year. This includes live stakes, all planted stems, and all natural/volunteer stems.
Plots	List of plots surveyed with location and summary data (live stems, dead stems, missing, etc.).
Vigor	Frequency distribution of vigor classes for stems for all plots.
Vigor by Spp	Frequency distribution of vigor classes listed by species.
Damage	List of most frequent damage classes with number of occurrences and percent of total stems impacted by each.
Damage by Spp	Damage values tallied by type for each species.
Damage by Plot	Damage values tallied by type for each plot.
Planted Stems by Plot and Spp	A matrix of the count of PLANTED living stems of each species for each plot; dead and missing stems are excluded.
ALL Stems by Plot and spp	and natural volunteers combined) for each plot; dead and missing stems are excluded.
PROJECT SUMMARY	
Project Code	95027
project Name	Junes Branch
Description	
River Basin	Little Tennessee
length(ft)	
stream-to-edge width (ft)	
area (sq m)	
Required Plots (calculated)	
Sampled Plots	5
