I. Executive Summary

The Newtown Stream and Wetland Restoration Site is located within the sub-basin 03-08-38 of the Catawba River Basin in Union County, North Carolina and contains Underwood Creek and one Unnamed Tributary (UT) to Underwood Creek. The restoration lengths of Underwood Creek (Main Channel) and UT to Underwood Creek (Tributary) are 1,273 and 4,075 feet, respectively, for a total project length of 5,348 feet (Figure 1). The project included restoration of 3.38 acres of riparian wetland and protection of an existing 0.15 acres of jurisdictional wetlands. The project site is owned by one property owner Mr. Frank W. Howey, Jr. The project is located within the HUC 03050103030020 (Lower Catawba Basin) of the South Atlantic-Gulf Region. NCDWQ classifies Underwood Creek (DWQ Stream Index Number 11-138-2-3-1) as class C. The 1.5 square mile watershed contributing drainage to the stream restoration segment is located in a rural setting. The land adjacent to the project streams is primarily used for agricultural practices and single family development. The floodplain is more confined in the upper reach of the project and opens up to a broad width for the majority of the project length. Vegetation typical of a Piedmont Alluvial Forest was planted throughout the conservation easement.

Project Goals:

- Improve water quality with the construction of stable stream banks and the establishment of a vegetated buffer
- Improve the stream function and habitat with the connection of the channelized and incised stream back to its floodplain
- ° Improve wetland hydrology with the functional uplift of the proposed channel
- Restore long-term stability with the restoration of channel pattern, profile and dimension
- [°] Improve in-stream habitat with the installation of brush toes, root wads, constructed riffles, log vanes and rock cross vanes to enhance pool depths

Project Objectives:

- ^o The restoration of 4,690 linear feet of Priority I, 558 feet of Priority II and 100 feet of Enhancement II in order to raise the stream bed elevation, reconnect the stream to its floodplain, restore pattern, and re-establish channel dimension on Underwood Creek and UT to Underwood Creek
- Restoration of 3.38 acres of wetlands through the functional uplift of the stream to improve wetland hydrology and the removal of depositional sediment from the wetland surface due to agricultural field soil wash
- Establish a minimum of 50 feet of riparian buffer along both sides of the entire stream length

Thirteen (13) vegetation plots were monitored using Level II of the CVS-EEP vegetation monitoring protocol (Version 4.2) which accounts for planted and natural stems. Counting only planted stems and excluding livestakes, there are 407 stems/acre. Counting both natural and planted stems, excluding live stakes, there are 859 stems/acre.

Ward Consulting Engineers, P.C.

2

The success criterion for planted woody species is 320 stems/acre after MY-03. A mortality rate of ten percent will be allowed after MY-04 (288 stems/acre), with another ten percent allowed after MY-05 (260 stems/acre). While all the vegetation plots combined meet the criteria for total planted stems, planted stem counts for plots 4, 6, 7, 8, and 11 were below the threshold requirements of 320 stems (Table 7). Plots 4, 7, and 8 exceeded the stem density requirements when including natural stems. Volunteers observed within the plot 4 and 7 were eastern cottonwood (*Populus deltoides*) trees. The eastern cottonwood is very abundant throughout the vicinity of the stream confluence and is sporadically abundant throughout the stream buffer corridor as in the vicinity of plot 7. Volunteers observed within plot 8 include eastern silverling (Baccharus halimifolia) and common elderberry (Sambucus canadensis). Other volunteer species observed within the conservation easement were black willow (Salix nigra), eastern sugarberry (Celtis laevigata), winged sumac (Rhus copallinum), and slippery elm (Ulmus rubra). Volunteer species densities are low within plots 6 and 11. Wetland hydrology is present and the herbaceous layer is dominant within the vicinity of Plot 6. Some planting may have been smothered by the herbaceous layer resulting in the low stem density. Planted species surviving within Plot 6 are river birch (Betula nigra), button bush (Cephalanthus occidentalis), green ash (Fraxinus pennsylvanica), and swamp chestnut oak (Quercus *michauxii*). Plot 11 is located within an area where the herbaceous layer is relatively sparse and wetland hydrology is absent. Planted species surviving are persimmon (Diospyros virginiana), green ash, swamp chestnut oak, and willow oak. The vegetation problem areas consist of areas with low stem densities and invasive exotic vegetation. Low stem densities were observed in the vicinity of plots 6 and 11 and in areas of the floodplain bench where herbaceous vegetation diversity was low and sparse. Some of these areas corresponds to areas where excavation of the new stream floodplain occurred. Soil compactness and nutrient deficiency may be a factor in the survival rate of woody stems in these particular areas of low stem densities. Five species of invasive exotics were observed in the conservation easement include Tree-of-heaven (Ailanthus altissima), Japanese stiltgrass (Microstegium vimineum), Chinese privet (Ligustrum sinense), Johnson grass (Sorghum halapense), and Asian dayflower (Murdania keisak). Chinese privet and Johnson grass stands within the conservation easement were treated with a foliar herbicidal spray during the MY-03 period resulting in individual stems of Chinese privet exhibiting defoliation with little new growth. Johnson grass was dying in most of the areas treated. Some areas of Johnson grass along the conservation easement limits still persist. Some living individual stems of Chinese privet were observed in and around the wetland reference site and along the margins of the adjacent woodlands beyond the conservation easement limits. The tree-of-heaven stands previously noted observed along the conservation easement boundary just northeast of plot 8 were dead with some re-sprouts in the immediate vicinity. Although these invasive exotic species are given different ranks of severity, the functionality of the project is not expected to be impaired significantly. These species will continue to be observed and treated as necessary.

3

	MY-03Vegetation Problem Areas					
VPA #	Station Number	Suspected Cause	Proposed Remedial Action			
1	See CCPV	Chinese privet is scattered in forested areas that were present during pre-construction.	Chinese privet has been treated throughout the CE. Persistence will be monitored and treated again if deemed necessary.			
2	See CCPV	Johnson grass is scattered in small patches and along the conservation easement boundary. The CCPV depicts areas where it is concentrated.	Johnson grass has been treated throughout the CE. Persistence will be monitored and treated again if deemed necessary.			
3	See CCPV	Japanese stiltgrass is concentrated in an area adjacent to woodlands where it escaped.	Japanese stiltgrass persistence will be monitored and treated if deemed necessary.			
5	See CCPV	Low stem densities were observed in patches throughout the conservation easement in areas where planted and natural stem densities were low.	Areas of low stem densities will be replanted in 2014			

Eight Remote Data Systems (RDS) groundwater monitoring gauges are located throughout the riparian wetlands within the conservation easement. There are a total of 3.38 acres of riparian wetland restoration and 0.15 acres of wetland preservation. According to the wetland groundwater gauges on site for MY-03, Gauges 1 through 8 met wetland hydrology criteria (Table 13). During the MY-04 period an additional three ground water monitoring gauges will be installed in select wetland restoration areas near the conservation easement boundary.

The monitoring reach of Underwood Creek is stable with little change to the stream pattern and profile. There was a much larger presence of water in the channel during MY-03 compared to MY-02. The months of June and July in 2013 had higher than normal rainfall. The cross sections for MY-03 compare well to the MY-02 cross section data. Pebble counts in the riffle cross sections show coursing of particle size. Some riffles surveyed in the longitudinal profile continue to adjust however no instability of the steam profile has occurred. The rills noted in the Current Condition Plan View (CCPV) occurred shortly after construction. They are currently not showing any further degradation and vegetation has begun to grow in this area. Beaver activity is present from the confluence of the tributary approximately 200 feet upstream. A beaver dam at station 18+20 was knocked down by monitoring personnel. The dams are causing back water and the submergence of the step grade control structures near the confluence. Beaver trapping is scheduled to occur before November 28, 2013.

The monitoring reach of UT to Underwood Creek also displays little change to pattern, profile or dimension. Along this 3,000 linear monitoring reach, 97 percent of the riffles are holding grade, a 2% increase from MY-02. Flowing water was not evident in the upper portion of the reach however water was present in some of the pools from station 9+50 to 11+25. The reach has been dryer during our surveys over the past two years

Ward Consulting Engineers, P.C.

4

which may be due to the data collection timing. The watershed will be investigated to determine if there has been an upstream impact that may be impacting the project site. No significant changes in the stream location or elevation was preformed with the restoration from station 1+00 through 8+00 that would have affected the stream hydrology. The channel from station 8+00 through 12+00 was relocated and elevated through a series of step structures. The soils will be evaluated in the relic channel location through this area in MY-04 to evaluate the post project soil hydrology. Flow will be documented in the channel next year at various times. EBX will install a minimum of two continuous flow devices prior to the start of the MY-04 growing season. There is no vegetation growing in the channel through the wooded enhancement area. Once the stream exits the wooded area and the tree canopy reduces the stream bank herbaceous vegetation is very dense. The vegetation has fallen into the channel forming mats in the channel bottom in areas. The vegetation is rooted to the bank and is easily pulled back out of the stream to the confluence.

A comparison of the cross section data shows little change in geometry between MY-02 and MY-03 for all sections but section 4. Cross section 4, a pool, has narrowed. The signification amount of vegetation present at the time of monitoring may have affected the data collected. The tree adjacent to cross section 1 has fallen and the root ball is partially exposed. This tree was mentioned in MY-02 as it was leaning on an adjacent tree. The root ball is in the floodplain and therefore is not compromising the channel banks at this time. The photo below shows the root ball of the fallen tree. Bank erosion was observed in two locations as noted in the MY-02 report. Four riffles showed signs of additional degradation in this monitoring year. The locations are noted on the CCPV. The overall longitudinal profile of the stream is stable. Beaver dams were present at three locations in the area from the confluence with Underwood Creek to a distance approximately 200 feet upstream. The beaver dams were broken down by monitoring personnel. The beaver dams are causing water to pond upstream of the channel.

	MY-03 Stream Problem Areas				
PA	Station	Suspected Cause	Proposed Remedial Action		
1	See CCPV	Bank erosion	Observe in MY-04 to see if stabilizes		
2	See CCPV	Point Bar Riling within the floodplain-occurred after construction	Not degrading further some vegetation has come into the area		
3	See CCPV	Degradation of some riffles from the previous monitoring year	Observe in MY-04 not causing any stream instability		
4	At confluence of streams – area of influence extends approximately 200 feet upstream both streams	Beaver activity – construction of beaver dams	Beaver removal		

Summary information/data related to the occurrence of items such as beaver or encroachment, and statistics related to performance of various project and monitoring elements, can be found in the tables and figures in the report appendices. Narrative background and supporting information formally found in these reports can be found in the mitigation and restoration plan documents available on EEP's website. All raw data supporting the tables and figures in the appendices is available from EEP upon request.

II. Methodology

Methodologies follow EEP monitoring report template Version 1.3 (01/15/10) and CVS vegetation monitoring protocol Version 4.2 (Lee et al 2008). Photos were taken with a digital camera. A Trimble Geo XT handheld unit with sub-meter accuracy was used to collect groundwater gauge locations, vegetation monitoring plot origins, and problem area locations. Cross sectional and longitudinal surveys were conducted using total station survey equipment. Data was entered into AutoCAD Civil3D to obtain dimensions of the cross sections and parameters applicable to the longitudinal profile. Reports were then generated to display summaries of the stream survey.

A. Vegetation Methodologies

Level II of the EEP/CVS protocol (Version 4.2) was used to collect data for MY-03. Data collected for these plots are in Appendix C.

B. Wetland Methodologies

Seven RDS groundwater monitoring gauges (1-3; 5-8) were installed in April of 2011. Gauge 4, the wetland reference gauge, was installed in February 2010. Gauges are downloaded bi- monthly to ensure proper function throughout the growing season. Data is provided in an Excel spreadsheet along with incorporation of local rainfall data provided by the NC State Climate Office.

C. Stream Methodologies

Stream profile and cross-sections were surveyed using total station equipment and methods, and plotted using AutoCAD Civil3D. The longitudinal profile was generated using the MY-00 alignment. Cross sectional data was extracted based on a linear alignment between the end pins. Cross section bankfull elevations for yearly comparisons are based on the baseline bankfull elevation established for each cross section.

Criteria, Definitions and Thresholds for Visual Stream Morphology Assessments

Major Channel	Channel Sub-				
Category	Category	Metric	Definitions	Cataloging Threshold	CCPV Depiction
1. Bed	 Vertical Stability (Riffle and Run units) 	 <u>Aggradation</u> - Bar formation/growth sufficient to significantly deflect flow laterally (not to include point bars) 	Aggradation refers to at least moderate increases in reach stored sediment. It is NOT simply constituted by minor fining of riffles or filling of pools at or below baseflow elevations. An aggrading reach is often characterized by sand or gravel bar formation(growth with associated fining of reach substrate and smoothing of the reach long profile. Barsiaggraded areas significant enough to deflect flow against barks should be catalogued. Repeat channel photopoints are a key tool in assessing project aggradation. (See photo exhibit 1 below for range of example bar development/aggradation)	Catalog only if feature has most of the characteristics described to the left (cell E11) and is at least 15 feet in length or 20% of the riftle/run length, whichever is less.	NA
		 <u>Degradation</u> - Number and size of evident downcuts within Riffle/Run units. 	Where projects have regularly-spaced angineered grade control, degradation/downcutting is expected only in short, decreed lengths. Tolfcateror include perched sill surviums, channel bed "Steps" in disyrich partern taterial, eledence of bad retreta at the bank toe (parent material may be exposed); mobilization of coarse riffle substrate in to pools downstream, and perhaps riffles with run morphology. Long profile surveys should support an assessment of bed degradation where the visual assessment and survey overlap.		Dark Red or Purple Color to be certain to distinguish from Mass Wasting Color Code
	2. Riffle Condition	1. Testure	Riffles should maintain a coarseness similar to the design distribution. Significant fining of the riffle surface indicates non attainment for the riffle. Repeat pebble courts should support an assessment of riffle fining where overlap occurs (see exhibit graphic 2 below describing embedding for gravel-cobble systems).	NA	NA
	3. Meander Pool Condition	1. Deoth Sufficient?	This metric is used to assess meander pools and also step-pools along a Rosgen B-type channel reaches. For stepped reaches the pools will be evaluated and tailed here and under the Habital Sub-Category below. The max pool bankfull depth should be 1.6 times the mean bankfull depth (Max Pool Depth: Maen Bankfull Depth >16.). The mean bankfull depth from the As-builtbaseline survey can be utilized to make this determination. Exhibit 3 provides residual pool depths using the 1.6 multiplier for a range of mean channel riffle depths that typify restoration projects.	NA	NA
		2. Lenath appropriate?	This metric will only be applied to meander pools. The meander pool length should be >30% of the ~ linear centerline distance between the tail of the upstream riffle and the head of the downstream rifle.	NA	NA
	4.Thalweg Position	 Thalweg centering at upstream of meander bend (Run)? 	This metric is used to characterize flow paths along riffle-run-pool transitions. The thalweg is expected to be against the outer bank in the bend apex, but vectors oriented towards the outer bank too far above the bend apex may indicate the potential for increased bank erosion. Similarly, the pool opticerifite transition is also expected to doemostrate flow path centering (Metric 4.2 below). The current-year thalweg rendered on the CCPV figure can assist in this assessment.	NA	NA
		2. Thalweg centering at downstream of meander bend (Glide)?	See Metric 4.1 above	NA	NA
2. Bank	1. Scoured/Eroding Bank	In order to better assess continued bank erosion risk, tailled bank segments are also characterized with respect to the	Banks with evident scour /erosion	Bank Minimum Height Length >6 6 3-6 8	Yellow.
	2. Undercut	proximity and integrated extent of stabilizing vegetation. Continued encision risk for a given bank instability object is essentially adjusted downwards by adjacent mature vegetation and/or stabilizing roots. One or more mature trees in close promithy (e.g. 10 feet or less) or dovicus integration of root mass within the bank failure are characteristics that would prompt the tallying of a given bank object into the additional sub-category related to risk of further instability (columns <u>14</u>) of the <u>actual data</u> . Essentially, the vegetative elements of rooting ensity and eight (e.g. from a BEH assessment)	Banks undercut/overhanging to the extent that mass wasting appears likely? Does NOT include undercuts that modest, appear sustainable/stable and are providing habitat.	<3 10 This table provides a guide for working thresholds for bank erosion cataloging/mapping based on bank height. For the bank height ranges above, the minimum length of	Orange.
	3. Mass Wasting	need to be considered here.	Bank slumping/calving/collapse?	bank to be mapped and tallied is specified. For example, where banks are <3 feet high, only map an unstable segment if it is \geq 10 feet. ⁵	Red.
3. Structures	1. Overall Integrity	The assessment of engineered structure performance should include all structures that provide grade control, bank protection, or habitat functions. These include Vanes, J-hooks, and rootwads, etc.	Bulk of structure physically intact with no disiodged boulders or logs?		Using callouts or some other means to maintain legibility, annotate structure with red "S" if structural failure has occurred
	2. Grade Control		Bed grade control maintained across the sill structure? No evident loss of bed elevation immediately upstream of structure? Some piping alone will not constitute a loss of grade control.		Using callouts or some other means to maintain legibility, annotate structure with red "G" if structure has lost grade control
	2a. Piping		Catalog structures lacking any substantial flow underneath sills or around arms?		Using callouts or some other means to maintain legibility, annotate structure with red "P" if significant piping has occurred
	3. Bank Protection		See exhibit 4 below for determining structural sphere of influence. If the amount of bank that is deemed to be actively eroding within the structures sphere of influence exceeds 15% of the total bank footage within the structures sphere of influence, then the structure should be classified as <u>not</u> providing adequate bank protection in the data table.		Using callouts or some other means to maintain legibility, annotate structure with red "B" if structure has failed to provide bank protection
	4. Habitat		Are pools maintained @ ~ Max Pool Depth : Mean Bankfull Depth > 1.6? For rootwads, habitat provision means interacting with baseflow and providing cover.		Using callouts or some other means to maintain legibility, annotate structure with red "H" if structure is not providing habitat

Exhibit 1. Examples of bar features warranting concerning related to cataloging item 1.1.1 of the assessment

Exhibit 2. Graphic depicting embedding of riffles with fine material

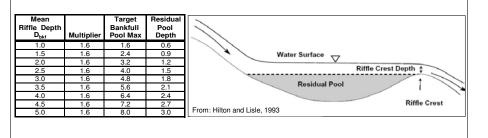

Progressing from top to bottom, the series of graphics to the left depicts the fining of interstial spaces between coarser particles. This describes increasing levels of embededness in riffles. The observer must have an understanding of the intended substrate distributions/texture of the bed for the projects riffles when assessing this. However, as a guideline for streams in the coarse gravel to cobble range, the 2nd panel from the top represents a visual guideline for the condition that would begin to elicit concern for this parameter, but still contains a good deal of coarse material. Progressing from that state to the conditions depicted in the the 3rd and 4th panel represents a visual que for significant emdedding.

From USEPA (EPA 841-B-97-003 - Nov 1997)

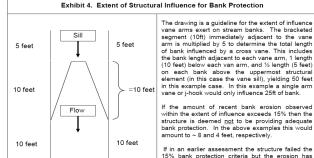

Exhibit 3. Residual Pool Depth Table - Relating 1.6 criterion for typical mean riffle depths to residual pool depths

This residual pool table was provided in the event the tracking of bankfull at each pool feature to estimate a Dmax was inconvenient. Estimating the residual pool depth by measuring the max pool depth to water surface and subtracting the water depth at the riffle head may provide a more convenient way under certain circumstances to estimate in the field. For this reason the exhibit table provides a relationship between the 1.6 criterion applied to mean riffle depth for the site and the resulting residual pool depths.

5 = The above was developed because of the need to have a threshold given the large number of performers and to avoid spending time trying to catalog and map small objects that if excluded would have minimal overall impacts on the performance percentages. It is a guide that tries to strike a balance between the obvious need to have a threshold, yet provide confidence that the site conditions are accurately represented. For example, a scenario where 1 object nearly exceeding the threshold were to occur every 100 feet of bank height (which would be a high frequency and unlikely) with a bank height of 5 feet, would vield an error of ~3%. However, if the observer is encountering a truly high number of objects just below the threshold in the above table (e.g. > 1 per 100 feet of bank channel on average) and is concerned that the exclsuion of such objects is going to misrepresent the site conditions, then judgement should be applied and objects below the threshold may be cataloged. If a rare condition as described does occur and the thresholds are not utilized then a table footnote explaining this should be included.

Lastly, given the increase in overall area and the implications to stability. greater banks heights required smaller threshold minimums.

criteria.

bank protection. In the above examples this would amount to ~ 8 and 4 feet, respectively. If in an earlier assessment the structure failed the 15% bank protection criteria but the erosion has subsequently stabilized, then the observer can use best professional judgment to determine if the structure is currently meeting the bank protection

Table 6 Vegetation Condition Assessment

Planted Acr

14.3

d	Acreage ¹	
---	----------------------	--

Vegetation Category	Definitions	Mapping Threshold	CCPV Depiction	Number of Polygons	Combined Acreage	% of Planted Acreage
1. Bare Areas	Very limited cover of both woody and herbaceous material.	0.1 acres	Pattern and Color	0	0.00	0.0%
2. Low Stem Density Areas	Woody stem densities clearly below target levels based on MY3, 4, or 5 stem count criteria.	0.1 acres	Pattern and Color	10	0.54	3.8%
			Total	10	0.54	3.8%
3. Areas of Poor Growth Rates or Vigor	Areas with woody stems of a size class that are obviously small given the monitoring year.	0.25 acres	Pattern and Color	0	0.00	0.0%
	Cumulative Tota					3.8%

Easement Acreage ²	16.43					
Vegetation Category	Definitions	Mapping Threshold	CCPV Depiction	Number of Polygons	Combined Acreage	% of Easement Acreage
4. Invasive Areas of Concern ⁴	Areas or points (if too small to render as polygons at map scale).	100 SF	Brown Line	13	0.33	2.0%
			-			
5. Easement Encroachment Areas ³	Areas or points (if too small to render as polygons at map scale).	none	Brown Line	0	0.00	0.0%

1 = Enter the planted acreage within the easement. This number is calculated as the easement acreage minus any existing mature tree stands that were not subject to supplemental planting of the understory, the channel acreage, crossings or any other elements not directly planted as part of the project effort.

2 = The acreage within the easement boundaries.

3 = Encroachment may occur within or outside of planted areas and will therefore be calculated against the overall easement acreage. In the event a polygon is cataloged into items 1, 2 or 3 in the table and is the result of encroachment, the associated acreage should be tallied in the relevant item (i.e., item 1,2 or 3) as well as a parallel tally in item 5.

4 = Invasives may occur in or out of planted areas, but still within the easement and will therefore be calculated against the overall easement acreage. Invasives of concern/interest are listed below. The list of high concern spcies are those with the potential to directly outcompete native, young, woody stems in the short-term (e.g. monitoring period or shortly thereafter) or affect the community structure for existing, more established tree/shrub stands over timeframes that are slightly longer (e.g. 1-2 decades). The low/moderate concern group are those species that generally do not have this capacity over the timeframes discussed and therefore are not expected to be mapped with regularity, but can be mapped, if in the judgement of the observer their coverage, density or distribution relative to native biomass, and the practicality of treatment. For example, even modest amounts of Kudzu or Japanese Knotweed early in the projects history will warrant control, but potentially large coverages of Microstegium in the herb layer will not likley trigger control because of the limited capacities to impact tree/shrub layers within the timeframes discussed and there of state with any frequency. Those species with the "watch list" designator in gray shade are of interest as well, but have yet to be observed across the state with any frequency. Those in *red italics* are of particular interest given their extreme risk/threat level for mapping as points where <u>isolated</u> specimens are found, particularly ealry in a projects monitoring history. However, areas of discreet, dense patches will of course be mapped as polygons, particularly for situations where the condition for an area is somewhere between isolated specimens and dense, discreet patches. In any case, the point or polygon/area feature can be symbolized to describe things like high or low concern and species can be listed as a map inset, in legend items if the number of species are limited or in the executive summary.

High Concern:		Low/Moderate Concern:				
Vines	Genus/Species	Shrubs/Herbs	Genus/Species	Shrubs/Herbs	Genus/Species	
Kudzu	Pueraria lobata	Japanese Knotweed	Polygonum cuspidatum	Japanese Privet	Ligustrum Japonicum

DESCRIPTION OF WORKSHEETS IN THIS DOCUMENT------

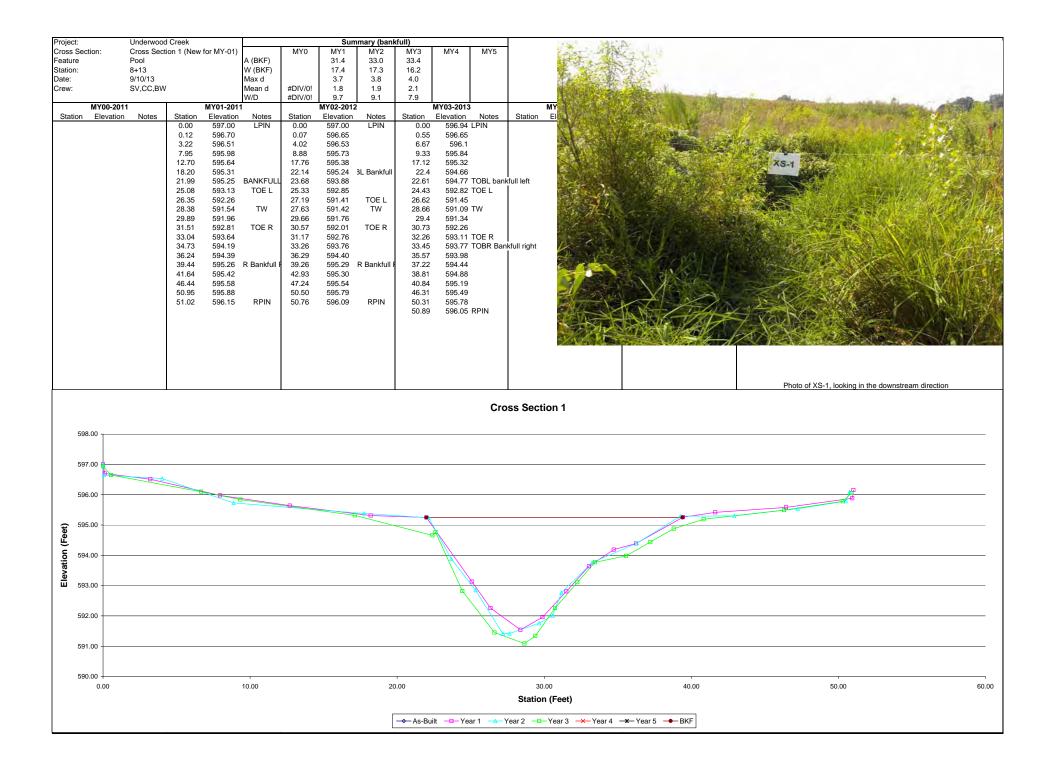

- Metadata Description of database file, the report worksheets, and a summary of project(s) and project data.
- Proj, planted Each project is listed with its PLANTED stems per acre, for each year. This excludes live stakes.
- Proj, total stems Each project is listed with its TOTAL stems per acre, for each year. This includes live stakes, all planted stems, and all natural/volunteer stems.
- Plots List of plots surveyed with location and summary data (live stems, dead stems, missing, etc.).
- Vigor Frequency distribution of vigor classes for stems for all plots.
- Vigor by Spp Frequency distribution of vigor classes listed by species.
- Damage List of most frequent damage classes with number of occurrences and percent of total stems impacted by each.
- Damage by Spp Damage values tallied by type for each species.
- Damage by Plot Damage values tallied by type for each plot.
- Planted Stems by Plot and Spp A matrix of the count of PLANTED living stems of each species for each plot; dead and missing stems are excluded.
- ALL Stems by Plot and spp A matrix of the count of total living stems of each species (planted and natural volunteers combined) for each plot; dead and missing stems are excluded.

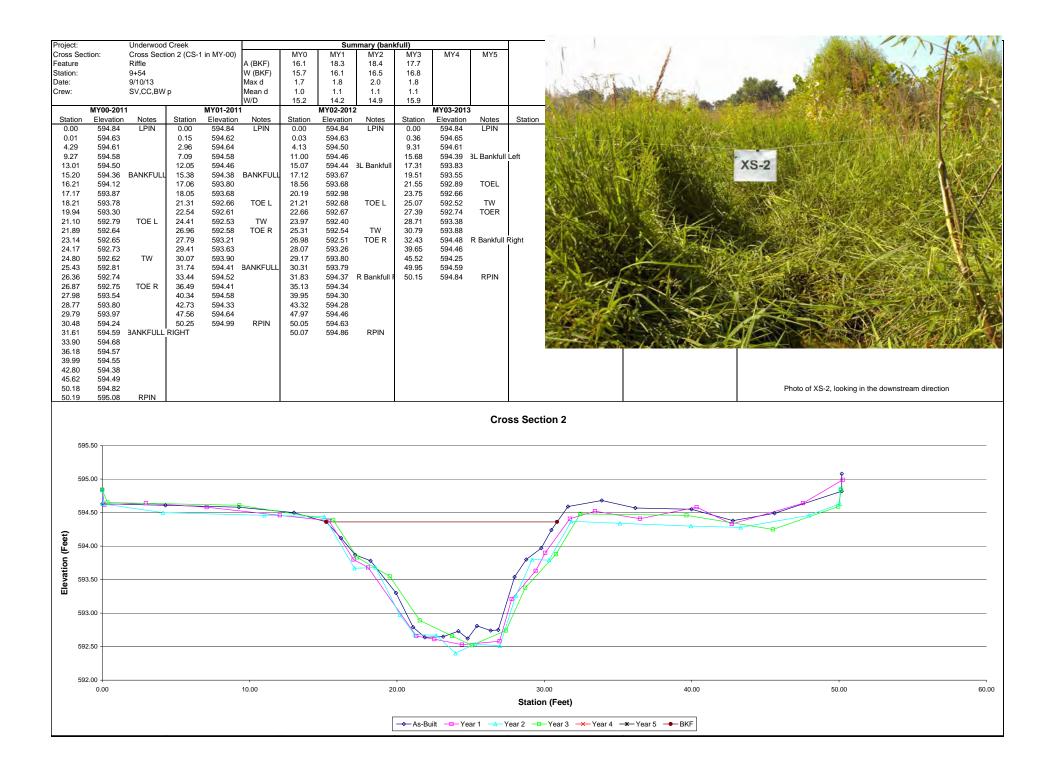

PROJECT SUMMARY	
Project Code	94150
project Name	Newtown Stream and Wetland Restoration
Description	Underwood Creek Stream Restoration in Union County
	southwest of Monroe, NC.
River Basin	Catawba
length(ft)	5317
stream-to-edge width (ft)	50
area (sq m)	49391.55
Required Plots (calculated)	13
Sampled Plots	13

1 = The distributions for these parameters can include information from both the cross-section surveys and the longitudinal profile. 2 = For projects with a proximal USGS gauge in-line with the project reach (added bankfull verification - rare).

3. Utilizing survey data produce an estimate of the bankfull floodplain area in acres, which should be the area from the top of bank to the toe of the terrace riser/slope.

4 = Proportion of reach exhibiting banks that are eroding based on the visual survey for comparison to monitoring data; 5. Of value/needed only if the n exceeds 3

1 = The distributions for these parameters can include information from both the cross-section surveys and the longitudinal profile. 2 = For projects with a proximal USGS gauge in-line with the project reach (added bankfull verification - rare).

3. Utilizing survey data produce an estimate of the bankfull floodplain area in acres, which should be the area from the top of bank to the toe of the terrace riser/slope.

4 = Proportion of reach exhibiting banks that are eroding based on the visual survey for comparison to monitoring data; 5. Of value/needed only if the n exceeds 3

1 = Riffle, Run, Pool, Glide, Step; Silt/Clay, Sand, Gravel, Cobble, Boulder, Bedrock; dip = max pave, disp = max subpave

2 = Entrenchment Class - Assign/bin the reach footage into the classes indicated and provide the percentage of the total reach footage in each class in the table. This will result from the measured cross-sections as well as visual estimates

3 = Assign/bin the reach footage into the classes indicated and provide the percentage of the total reach footage in each class in the table. This will result from the measured cross-sections as well as the longitudinal profile

Footnotes 2,3 - These classes are loosley built around the Rosgen classification and hazard ranking breaks, but were adjusted slightly to make for easier assignment to somewhat coarser bins based on visual estimates in the field such that measurement of every segment for ER would not be necessary. The intent here is to provide the reader/consumer of design and monitoring information with a good general sense of the extent of hydrologic containment in the pre-existing and the rehabilitated states as well as comparisons to the reference distributions. ER and BHR have been addressed in prior submissions as a subsample (cross-sections as part of the design survey), however, these subsamples have often focused entirely on facilitating design without provide at thorough pre-constrution distribution of these parameters, leaving the reader/consumer with a sample that is weighted heavily on the stable sections of the BHR at riffles beyond those subject to cross-sections and therefore can be readily integrated and provide a m

1 = Widths and depths for monitoring resurvey will be based on the baseline bankfull datum regardless of dimensional/depositional development. Input the elevation used as the datum, which should be consistent and based on the baseline datum established. If the performer has inherited the project and cannot acquire the datum used for prior years this must be discussed with EEP. If this cannot be resolved in time for a given years report submission a footnote in this should be included that states: "It is uncertain if the monitoring datum has been consistent over the monitoring history, which may influence calculated values. Additional data from a prior performer is being acquired to provide confirmation. Values will be recalculated in a future submission based on a consistent datum if determined to be necessary."

Table 13. Wetland Criteria Attainment 2010-2013

a – Gauge installed April 23, 2011 –197 days of growing season monitored

b - Gauge installed April 22, 2011 –198 days of growing season monitored

c – Gauge installed February 20, 2010; Data missing due to gauge failure - 217 days of growing season monitored

d - Gauge installed May 24, 2011 - 166 days of growing season monitored

e - Gauge installed August 13, 2011 -85 days of growing season monitored

f - Report produced prior to end of growing season -223 days of 2012 growing season monitored

g - Data missing due to gauge failure; 219 days of growing season monitored

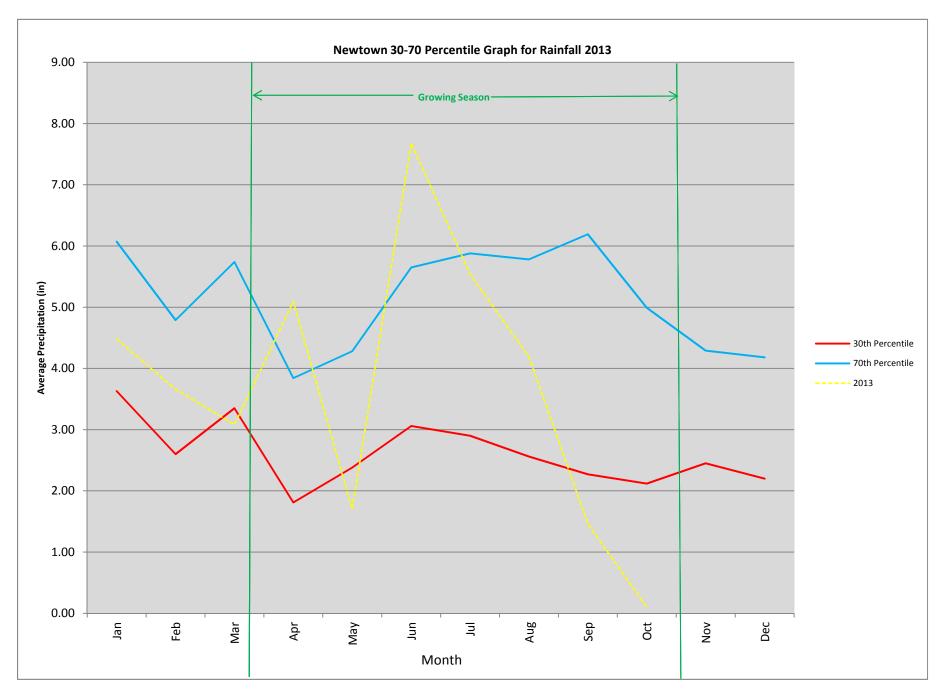

h - Data missing due to gauge failure; 181 days of growing season monitored

i - Report produced proper to end of growing season - 209 days of 2013 growing season monitored

j - Data missing due to gauge failure; 130 days of growing season monitored

Growing Season: March 23 to November 6 (source: http://www.wcc.nrcs.usda.gov/cgibin/state.pl?state=nc)

Groundwater levels should be within 12 inches of the surface for at least 6.3% of the growing season to meet wetland hydrology success criteria. Union County has a growing season of 221 days (March 23-October 6). Therefore groundwater levels must be within 12 inches of the soil surface for a minimum of 14 consecutive days within the growing season to meet wetland hydrology success criteria. All of the wetland groundwater gauges exhibit hydroperiod criterion that exceeds the minimum 6.3% as described in the Baseline Monitoring Document and As-Built Baseline Report.

2013 Rain Data: Station KCLT (http://www.nc-climate.ncsu.edu/services/request.php)
