Executive Summary

The Powell Property Wetland and Stream Mitigation Site is a headwater riverine wetland and stream mitigation project located southeast of Powellsville, in Bertie County, North Carolina. It was constructed by Albemarle Restorations, LLC, under contract with EEP to provide 48.4 acres of riverine wetland mitigation credits and 3,310 linear feet of stream mitigation credits in the Chowan River Basin. Construction activities, in accordance with the approved restoration plan, began in June of 2008, and were completed in January of 2009. Planting took place in January of 2009.

Ten of the twelve gauges on the project site indicated successful wetland hydrology for a minimum of 5% of the growing season. Hydrology around gauges 7A and 7B continues to develop. Those two gauges, which are situated higher in the landscape than any of the other gauges are more sensitive to interrupted rainfall patterns. Two separate flow events were documented during 2012.

A total of ten vegetation monitoring plots are located on the site, seven in the riverine wetland areas and three more situated to monitor the swamp run vegetation. One plot is entirely within the boundaries of the swamp run and two more are located so as to share both land forms. Each plot is a 10m X 10m square, as recommended by the CVS-EEP protocol for recording vegetation sampling. All ten plots met the fourth year survival success criterion which is a minimum of 260 stems per acre.

Table ES-1 shows the levels of success attained by each of the water level monitoring gauges and the vegetation plots. The success criterion for hydrology is maintained groundwater levels within 12 inches of the soil surface for 5% to 8% of the growing season (12 to 19 consecutive days). Table C-1 in Appendix C has a detailed breakdown of hydrologic success.

Table ES-1. Project Success Summary

Gauges show longest hydroperiod as % of growing season, Plots show Stems per Acre							Percent

Gauge values shown in red did not meet minimum of 5% of the growing season

I. <u>Project Background</u>

1.0 Project Objectives

The goal of the Powell Property Mitigation Project was to create a riverine wetland system typically found in the middle to upper reaches of first or zero order tributary systems. The project is to serve as compensation for wetland loss in the Chowan River Basin. The restoration plan was developed and implemented to eliminate pattern drainage and restore topography and hydrology that more closely resembled that of similar undisturbed land. Construction resulted in the development of a broad, branched, frequently flooded swamp run following a historical path as evidenced by archived aerial photographs and signature topography. Subsequent planting was designed to restore a wetland forest ecosystem that is typically found in the immediate area characteristic of similar soils, topography and hydrology.

Ecological benefits of the restored riparian headwater system and its associated riverine wetlands are the following:

- 1. Water quality improvements, including nutrient, toxicant and sediment retention and reduction, increasing dissolved oxygen levels, as well as reducing excessive algae growth, and reducing surface water temperatures in receiving waters by providing permanent shading in the form of a shrub/scrub and forested headwater wetland system.
- 2. Wildlife habitat enhancement by adding to the existing adjacent forested areas creating a continuous travel corridor between habitat blocks and providing a wide range of habitat areas (open water, emergent, shrub/scrub and forested) for amphibians, reptiles, birds, insects and mammals.
- 3. Flood flow attenuation during storm events which reduces sedimentation and erosion downstream, and improves long term water quality within the Chowan River.
- 4. Passive outdoor recreation and educational opportunities for the landowner and the surrounding community.

2.0 Project Structure, Restoration Type, and Approach

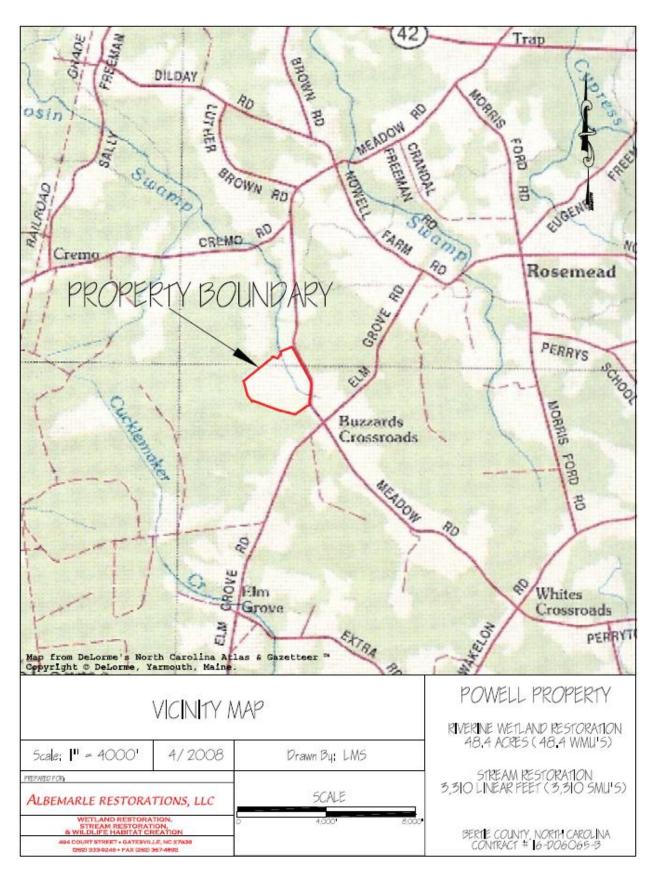

Table I lists the estimated wetland acreage to be restored on the Powell Property. The mitigation plan provides for the restoration of 48.4 acres of riverine wetlands and 3,310 linear feet of stream (swamp run) restoration. Prior to construction, the easement area was used entirely for row crop agriculture, primarily soy beans, corn, cotton and tobacco. The agricultural fields were drained by several ditches that traversed the site and one main drainage ditch that emptied into Quioccosin Swamp. Construction was done in accordance with the approved restoration plan and completed in January of 2009. Native tree and shrub species were planted in January of 2009 and the resulting riverine system is designed to emulate natural swamp run systems found within the Chowan River Basin.

Table I. Project Restoration Components Powell Wetland and Stream Mitigation Site/EEP #D06065-B						
Post Pre-Existing Acres/Linear Restoration Type Feet Post Construction Acres/ Linear Feet Restoration Type Feet Restoration Type Post Construction Acres/ Linear Restoration Type Feet Restoration Type Post Construction Acres/ Linear Restoration Type Feet Restoration Type Restora						
Riverine Wetland	0.0 acres	48.4 acres	1:1	48.4 WMUs		
Stream (Swamp Run)	0.0 linear feet	3,310 linear feet	1:1	3,310 SMUs		

3.0 <u>Location and Setting</u>

The Powell Property Mitigation Site is located in Bertie County, just north of Buzzard's Crossroads on Meadow Road (approximately 4.6 miles southeast of Powellsville). The easement area is situated on the eastern portion of the Powell farm and adds contiguous swamp run and forested wetlands to Quioccosin Swamp which flows to the Wiccacon River, a tributary of the Chowan River. The surrounding area is primarily forest and agricultural land with residential properties as a minor component.

Figure 1 is a location map for the project site. Directions to the site are as follows: from Powellsville (Hwy. 42), travel south on Sally Freeman Rd., turn left on Dilday Rd., right on Luther Brown Rd., then right on Meadow Rd. Access to the site is approximately 2 miles from this intersection, on the right.

4.0 Project History and Background

Table II provides the history of data collection and actual completion of various milestones of the Powell Property Wetland Mitigation Site.

5.0 Monitoring Plan View

A total of twelve water level monitoring gauges are installed across the site. These gauges are suspended in two-inch pvc pipe that is set from two to four feet vertically in the ground. The gauges have been located to assess the groundwater levels throughout the year at various elevations and topographies within the site. Two more gauges are installed in an offsite riverine wetland area to serve as references for a naturally functioning riverine wetland and headwater swamp run. In addition, there is a rain gauge onsite to capture and record precipitation.

Vegetation monitoring is accomplished by surveying the ten permanent sampling plots. The plots are ten meters square and are situated to give an accurate sample of the planted and natural woody vegetation in both the riverine and swamp run communities. For each site, the data recorded matches that required of the CVS-EEP Protocol for Recording Vegetation, v 4.0, 2006, level 1-2.

Figures 2 and 3 provide plan views of the site showing the location of all monitoring features including gauges, sampling plots and the rain gauge as well as the vegetative communities.

II. Project Condition and Monitoring Results

1.0 <u>Vegetation Assessment</u>

The vegetation success criterion was developed in accordance with the CVS-EEP protocol. The Powell project was designed to include both riverine and bottomland hardwood plant communities. The project was planted with a mixture of tree and shrub species that would resemble that of naturally occurring swamp runs and adjacent riverine wetlands in the local area. The run and area immediately adjacent were planted heavily with cypress, willow and tupelo. The riverine wetland zone beyond the swamp run is populated by a broader mix of native hydrophytic tree and shrub species. The species mix was based on the vegetation noted at the reference site and all species are classified from FAC to OBL (Table V). The site was planted at a rate of 600 stems per acre in January of 2009.

Table V. Species by Community Type							
Powell Wetland and Stream Mitigation Project/EEP #D06065-B Total Forested Wetland 55.9 Acres							
Common Name	Scientific Name	Wetland Indicator Status

Sweetbay Magnolia	Magnolia virginiana	FACW+					

1.1 Vegetation Discussion and Problem Areas

All ten plots met the Year 5 success criterion of a minimum of 260 stems per acre. Over the entire project, the survival rate averaged 404 live stems per acre. Annual mortality continues to be light; the survival rate in 2010 averaged 429 stems per acre. Growth continues to be very good as well as is the overall health of the forested community.

2.0 Wetland Assessment

The hydrologic success criterion for any gauge is to achieve a minimum of 12 to 19 consecutive days where the groundwater level is within 12 inches of the soil surface during the growing season. This represents 5% to 8% of the growing season which for this site runs from March 22 to November 8, a period of 231 days (WETS Table for Lewiston, NC). All but two gauges, 7A and 7B, measured a successful hydroperiod during the year. Gauges 7A and 7B both measured a 3% hydroperiod.

2.1 Wetland Discussion and Problem Areas

The deficiency shown at Gauges 7A and 7B is directly linked to the rainfall patterns at the beginning and end of the growing season when successful hydrology is most likely to occur. There was a cumulative rainfall deficit of .99" from January through April. From April 1 through April 19, only .4 inches total were recorded on site. Since these two gauges are located highest in the landscape, the rainfall pattern must show some continuity during this critical time in order for them to record successful hydrology. The same pattern of sporadic rainfall occurred at the end of the growing season. Rainfall in October was nearly twice normal, but most of that fell during Hurricane Sandy at the end of October. Total rainfall from November 1st through the 26th totaled only .65". All of the gauges that indicated successful hydrology did so at the beginning of the growing season this year. Gauges 1 and 4 showed the same patterns as 7A and 7B but due to their location in the landscape they showed successful hydrology at 8% and 7% respectively.

Because of concerns about soil compaction around Gauges 6 and 7 in 2009 and 2010, those areas of the project were subsoiled in September of 2010 and replanted in January of 2011. Gauges 7A and 7B were added to enhance the accuracy of data collection. Gauge 6 showed a 26% hydroperiod in 2011, but only an 8% hydroperiod in 2012, indicating the subsoiling successfully corrected any compaction problems in that area, but rainfall patterns continue to have a greater effect on success. Again, location in the landscape appears to be the issue as Gauge 6 sits a foot lower in elevation and closer to the swamp run than either 7A or 7B. Gauge 7 also sits at the same elevation as Gauge 6 and is also nearer the swamp run than 7A and 7B and Gauge 7 showed an 8% hydroperiod this year. The relative positions of these gauges serve to further affirm that adequately timed rainfall at the beginning and end of the growing season is necessary in order for Gauges 7A and 7B to show successful hydrology.

2.15 **Flow**

Refer to Figures F1 and F2 which are composite charts for Gauges 2, 5 & 9, for the following discussion of evidence of flow within the swamp runs. Figure F1 is a composite chart showing a period of flow in March, 2012. Figure F2 is a composite chart showing flow in late October, 2012 after Hurricane Sandy produced enough rainfall to briefly recharge the watershed. As can be seen on the hydrographs, prior to that storm, the site was very dry. Both flow events were video documented and those files are included on the CD accompanying this report.

By comparison, Reference Gauge 11, which is in the center of the reference swamp run, showed no water flowing in October. This was confirmed during a site visit in November; the reference run was found to be dry and both reference gauges were empty. The project area appears to be more sensitive to rainfall, producing flow patterns that may be shorter lived, but more frequent than the reference area which may take longer to recharge, but continues to flow for longer periods.

3.0 Project Success Discussion

After the fourth year of monitoring and corrective action in the form of subsoiling to correct hydrology issues, the wetland hydrology on the Powell project shows indications of successful restoration. Specifically, the hydrology within the swamp run has been restored and the project is functioning like a natural riparian headwater system. Flow of water across the site was successfully measured and documented on two separate occasions in 2012.

The reference gauges are measuring very similar above- and below-ground water patterns at the reference site as those measured on the project, confirming that the site is functioning like a natural system. Overall tree survival and growth is good.

Listed below are the field indicators from the approved mitigation plan that are to be used to help substantiate flow. Those shown in <u>blue</u> were observed and/or video or photo documented since 2009.

- A natural line impressed on the bank
- Shelving
- Changes in soil characteristics
- Destruction of terrestrial vegetation
- Presence of litter and debris
- Wracking
- Vegetation matted down or absent
- Sediment sorting
- Leaf litter disturbed or washed away
- Scour
- Deposition
- Bed and bank formation
- Water staining
- Change in plant community

High water marks on bank vegetation were noted and photographed during December of 2009 after heavy rainfall. Matted vegetation was noted and photographed in April of 2010, the remnants of winter flooding. Further evidence of flow is deposition of small detritus after flow events as well as some scouring in the mid portion of the project. Wracking can be seen among the vegetation downstream after heavy rains. Sediment sorting can also be seen after heavy rains. Channelization at the midpoint of the project continues to develop.

III. Methodology Section

Year 4 monitoring for the Powell project occurred in September of 2012. Monitoring and vegetation sampling procedures were established in the mitigation plan for this project and no deviations were made.

5% of growing season is 12 days, 8% is 19 days Hydrology is deemed successful if longest consecutive hydrologic period meets minimum of 5% of the growing season Gauges 7A and 7B were installed in Year 3 (2011)

Cumulative rainfall deficit through April 2012 was .99". Late spring and summer rainfall was good, but due to timing did not help maintain hydrology. Except for Hurricane Sandy late in October, fall rainfall was very light.
