1.0 EXECUTIVE SUMMARY / PROJECT ABSTRACT

The North Carolina Ecosystem Enhancement Program (EEP) restored and preserved wetlands and preserved streams at the Roquist Wetland Site in Bertie County, North Carolina. The 3,926 acre site is located within the USGS 8-digit HUC 03010107 of the Roanoke River Basin. The project restored 45.2 acres of wetland and preserved an additional 3,776 acres of wetland and 3,660 linear feet of stream channel. Project construction was completed in 2008. The project goals and objectives are listed below.

- Restoration of 45.2 acres of previously ditched and filled nonriparian wetlands.
- Preservation of 3,366 acres of nonriparian wetlands.
- Preservation of 390 acres of high quality nonriparian wetlands.
- Preservation of 20 acres of riparian wetlands.
- Preservation of 3,660 linear feet of stream channel.

The restored wetlands were planted with fifteen different species of bare root trees and shrubs. Baseline vegetation monitoring was delayed until the end of the first growing season. Ten vegetation monitoring plots were established during the first monitoring year, following the CVS-EEP protocol. Because of this the data reported in the *Roquist Wetland Restoration Site Phase I Mitigation Report* is first year monitoring data and not baseline data as would typically be in the mitigation plan. The second year monitoring found a site average of 133 stems/acre, with seven of the ten vegetation monitoring plots having planted stem densities less than the success criteria of 260 stems/acre. Low planted stem densities were also found during the first year of monitoring, but due to the large amount of volunteer woody stems found in the plots, it is likely that volunteer vegetation will successfully vegetate the site throughout the monitoring period. The site's average stem density including volunteers is 911 stems/acre, with only three of the ten vegetation plots having densities less than 260 stems/acre. First year monitoring reported that wild hogs significantly damaged the planted vegetation, resulting in increased mortality.

To monitor wetland hydrology 12 gauges were established. Seven of these gauges (2, 3b, 5, 9, 11b, 14, and 15) were installed in restored wetlands. The remaining five gauges (1, 4, 6, 13, and 12) are reference gauges that were installed in existing wetlands, and are paired with a gauge in an adjacent restoration area. Two of the restoration gauges (14 and 15) are not paired with reference gauges. During the second growing season all of the restoration gauges met the success criteria of having saturated soil conditions occurring within 12 inches of the ground surface for a minimum of 12.5% (29 days) of the 231 day growing season (March 22 to November 8) during average climatic conditions, or having the hydroperiod in the restoration areas be within 20% of the corresponding reference hydroperiod during drought conditions. The daily rainfall data obtained from a local weather station shows that the area had average rainfall during the 2009 growing season.

Summary information/data related to the occurrence of items such as beaver or encroachment and statistics related to performance of various project and monitoring elements can be found in the tables and figures in the report appendices. Narrative background and supporting information formerly found in these reports can be found in the mitigation and restoration plan documents available on the EEPs website. All raw data supporting the tables and figures in the appendices are available upon request.

2.0 METHODOLOGY

The Level 2 of the CVS-EEP protocol (<http://cvs.bio.unc.edu/methods.htm>) was used to collect vegetation data from the Roquist site this year, the second year of monitoring.
