I. EXECUTIVE SUMMARY

The South Muddy Creek Tributaries restoration project is located near Dysartsburg in McDowell County, North Carolina. The stream channels included in this project are designated as Tributaries A, A2, B and C. Prior to restoration, Tributaries A and A2 were drainage channels that had experienced modification in the form of ditching and vegetative management. Tributaries B and C were natural channels that were in a degraded condition attributed to head-cutting and streambank erosion exacerbated by cattle intrusion. The project consists of a combination of Priority 1 and Priority 2 Restoration and Enhancement Level 1. The project goal for the restoration plan, completed in 2005, was to re-establish geomorphic features consistent with natural stream channel characteristics. Elements of the restoration design included grade control and bank stabilization using natural materials and native plantings, reconnection of the channels to functional floodplains, and the incorporation of instream habitat features including riffle/pool complexes to re-establish, sort and transport substrate materials. The following report documents the Year 2 Annual Monitoring for this project.

Vegetative monitoring was completed in September 2007 using the methodology of the Carolina Vegetation Survey. Stem counts completed in 30 vegetation plots showed an average density of 323 stems per acre for the site, which meets the success criteria of 320 stems/acre after three years of monitoring. Fourteen of the thirty vegetation plots fall below this threshold number. These plots are scattered throughout the project area. The stem count for Year 2 represents 83% survival from the previous year, when supplemental trees and shrubs were planted to bring the average live stem density to 390 stems per acre. It is likely that the spread of *Sericea lespedeza* throughout much of the project corridor has hindered the growth and survival of woody vegetation. This species is a common component of pasture mixes, and likely spread into the project area from the surrounding pasture lands. Management is planned for the spring of 2008 to combat this species and will include herbicide treatments, sprayed in a manner to minimize the impact on planted woody vegetation. After management of this species is conducted in the spring of 2008, another round of remedial tree plantings will be conducted. These plantings are intended to bring the site back into compliance with the 320 stems per acre minimum, and to replace any trees inadvertently impacted by the herbicide treatments.

Monitoring of the stream identified some problem areas along the tributaries of South Muddy Creek, including areas of aggradation and bank scour. The problem areas along the streams appear to be limited to isolated areas on each reach. Areas of erosion have resulted in bank scour along meander bends or around riffles and log sills at some locations. A few areas of aggradation have resulted in bar formation in the channel near riffle areas. With the exception noted, the restored stream channels remain stable. In addition, the extensive vegetative development in Year 2 has increased streambank stability.

Bedform features continue to evolve along the restored reaches as shown on the long-term longitudinal profiles. Riffle lengths and slopes are stable. Pool to pool spacings are representative of reference reach conditions, adjusted for drainage area and bankfull width. The pools have developed excellent glide features, providing spawning habitat for native fishes and riffle substrates conducive to benthic macro-invertebrate populations to re-emerge. Of interest, is the change (median decrease) in pool to pool spacings between Year 1 and Year 2 on Upper Tributary A and to a lesser degree on the other long-term monitoring profiles. This bedform adjustment may be attributed to extended drought during the summer of 2007 (low flow conditions) and minimal flushing of sand-sized particles through the project reaches. Future monitoring may confirm this hypothesis. Comparison of As-Built, Year 1 and Year 2 long-term stream monitoring show successive increases in channel-floodplain connectivity and increasingly stable channel dimensions, interpreted from width/depth ratios, entrenchment ratios, bank height ratios, etc. as shown on the long-term monitoring cross-sections. Median particle sizes of the stream channels

ranged from fine to coarse gravel in the riffle/run areas, and silt to medium sand in the pool/glide areas. Remedial maintenance work on the restored reaches is not planned at this time.

II. PROJECT BACKGROUND

A. Location and Setting

The project is located in McDowell County, North Carolina, approximately two miles south of Interstate 40, between Marion and Morganton near the community of Dysartsburg. The tributaries lie east of Muddy Creek Road, north of Pinnacle Church Road and west of Dysartsburg Road, as shown on Figure 1. The stream channels included in the project are designated as Tributaries A, A2, B and C. Tributaries A, B and C confluence directly with South Muddy Creek. Tributary A2 confluences with Tributary A.

Directions to the project site are as follow:

From Marion, follow Interstate 40 east to Dysartsburg Road (Exit 94). Turn right onto Dysartsburg Road to travel south for approximately 2 miles to Pinnacle Church Road. Follow Pinnacle Church Road to Muddy Creek Road, and turn right. The project site is on the east side of the road. This is private property; access to the stream corridor is limited to the dedicated ingress/egress included as part of the recorded Conservation Easement. Coordination with the property owner is encouraged prior to accessing the property.

B. Project Structure, Mitigation Type, Approach and Objectives

Pre-restoration land use surrounding the project tributaries consisted of agricultural croplands along Tributaries A and A2 and cattle pastureland along Tributaries B and C. The upper reaches of Tributaries A2, B and C were characterized by a mix of pastureland and limited wooded corridor. Tributaries A and A2 were drainage channels that had experienced modification in the form of ditching and vegetative management prior to restoration. Tributaries B and C are natural channels that, prior to restoration, were in a degraded condition attributed to head-cutting and streambank failure and erosion exacerbated by cattle intrusion and associated hoof shear. All of the tributary channels, prior to restoration, had narrow or denuded riparian corridors.

Tributaries A, A2 and B were surrounded by either cropland or pasture with no significant buffer prior to restoration. Tributaries B and C lacked cattle intrusion fencing that adversely impacted streambank stability. Tributary C was less degraded, prior to restoration, in that it had a significant wooded riparian corridor on the south (left) bank with well sorted and well graded bed materials. However, Tributary C was impacted by a significantly degraded riparian corridor on the north (right) bank, with numerous locations of streambank erosion and failure associated with cattle intrusion.

Restoration of the project streams re-established geomorphologic features consistent with natural stream channel characteristics. Results achieved are listed below.

- Bankfull channels constructed with the appropriate geometries to convey bankfull flows and transport suspended and bedload materials available to the streams.
- Stable channel patterns consistent with natural streams in the region.
- Grade control and bank stabilization features that enhance environmental attributes of the stream channels through the use of natural materials and native plantings.
- In-stream habitat features, including riffle/pool complexes to re-establish, sort and transport substrate materials available to the streams.
- Reconnection of project stream channels to functional floodplains.
- Extensive indigenous instream and riparian revetment.

MONITORING
FIGURE 1

Date: September, 2007

Job No. 2004-2359

Scale: 1" = 2000'

Restoration of Tributaries A, A2 and B was accomplished through the modification of the existing pattern, profile and dimension of the tributary channels to a stable condition. The restored channels are on an alignment that is offset from the pre-existing stream channels. Post-construction, the existing tributary channels were abandoned and filled. Restoration along these reaches was either Priority 2, where the elevation of the floodplain was lowered through excavation to re-connect it to the restored stream channel, or a combination of Priority 2 and Priority 1, where the floodplain was lowered and the stream thalweg was raised above the existing channel profile.

The lower reach of Tributary A has a low gradient, which flattens to 0.0012 ft/ft. Due to a relatively flat profile gradient, a series of successive pool and riffle complexes was not proposed. Instead, the restored stream channel has constructed point bars on the inside of meander bends at pool locations and is transporting its bedload through the run/pool complexes as the bed form of the channel naturally evolves. The steeper gradient associated with the restored stream channels along Tributaries A2 and B allowed the construction of a sinuous channel with constructed riffle/pool sequences.

Enhancement Level I was accomplished along one of the reaches on Tributary A by modifying the profile and dimension of the channel. Along this segment, improvements were constructed along the alignment of the existing stream channel. Enhancement Level I on Tributary C provides bank stabilization, through cattle exclusion, with one hard-engineered, fenced and controlled cattle access point for watering, combined with continuous preservation of the riparian buffer. Stabilization was accomplished by re-grading steep, undercut channel banks, and the use of jute matting and live plantings.

An important component of the restoration of Tributaries B and C is cattle exclusion. As mentioned previously, these channels are adjacent to pastureland, where cattle frequented the streams for drinking water. Prior to restoration, the cattle accessed the streams at random locations and, in doing so, denuded and destabilized the pre-existing channel banks. The restoration of Tributary B includes fencing that permanently excludes cattle from the stream corridor. The fencing along Tributary C limits cattle access to a single point along the stream reinforced with stone underlain by non-woven geotextile to prevent degradation that would otherwise occur. All fencing has been placed at the outer edge of the conservation easement.

Information on the project structure and objectives is included in Tables I and II as follows:

Table I. Project Structure Table South Muddy Creek Tributaries Restoration / EEP Project No. D04006-01

III. PROJECT CONDITION AND MONITORING RESULTS

A. Vegetation Assessment

1. Soil Data

The project area is contained within the Iotla-Braddock-Rosman-Potomac soil association. This soil association typically consists of nearly level to very steep, somewhat poorly drained soils, which have a predominantly loamy, clayey or sandy subsoil formed in alluvium on floodplains and stream terraces (USDA, NRCS 1995).

The majority of Tributary A is mapped within Iotla sandy loam with 0-2% slopes, occasionally flooded. The upstream portion of the tributary flows through additional soil units including Elsinboro loam with 1-4% slopes, rarely flooded, Braddock clay loam with 6-15% slopes, eroded and Hayesville-Evard complex with 15-35% slopes. Tributary A2 is mapped in Iotla sandy loam. The portion of tributary B that is included in the restoration is mapped within Dillard loam, 1-4% slopes, rarely flooded. The portion of Tributary C that is included in the restoration is mapped within the Iotla sandy loam unit.

Data on the soils series found within and near the project site is summarized in Table VI.

**Table VI. Preliminary Soil Data
South Muddy Creek Tributaries Restoration / EEP Project No. D04006-01**

Series	Max. Depth (in.)	% Clay on Surface	K ¹	T ²	% Organic Matter
Braddock clay loam (BrC2)	80+	27-40	0.32	5	0-2
Dillard loam (DdB)	80+	10-15	0.32	5	4-8
Elsinboro loam (EsB)	60+	8-18	0.28	5	1-3
Hayesville-Evard complex (HeD)	60+	7-25	0.24-0.28	5	1-5
Iotla sandy loam (IoA)	60+	12-18	0.2	5	4-8

¹Erosion Factor K indicates the susceptibility of a soil to sheet and rill erosion, ranging from 0.05 to 0.69.

²Erosion Factor T is an estimate of the maximum average annual rate of soil erosion by wind or water that can occur without affecting crop productivity, measured in tons per acre per year.

2. Vegetative Problem Areas

Vegetative Problem Areas are defined as areas either lacking vegetation or containing populations of exotic vegetation. All problem areas identified during Monitoring Year 2 are summarized in Table VII. Photographs of the vegetative problem areas are shown in Appendix A. There are also a few locations where the density of planted woody stems is not high enough to meet the required stem counts. Densities of planted woody species are discussed in the Stem Counts section of this report.

**Table VII. Vegetative Problem Areas
South Muddy Creek Stream Restoration / EEP Project No. D04006-01**

Feature/Issue	Station # / Range	Probable Cause	Photo #
Invasive Population	Throughout: See VPA Plan View	<i>Sericea lespedeza</i> : encroachment from pasture	VPA 1, VPA 2

The only type of vegetative problem is the spread of an invasive species, *Sericea lespedeza*. This species is a common component of pasture mixes, and as this project is adjacent to pasture lands, it likely spread into the project area from the surrounding landscape. The spread of the species is extensive throughout the project corridor. Management is planned for the spring of 2008 to combat further spread and attempt to eradicate much of this species from areas where it has negatively impacted the survival of planted woody vegetation. This management will include herbicide treatments, sprayed in a manner to minimize the impact on planted woody vegetation. Management of the woody vegetation is discussed in the Stem Counts section of this report. Further spraying will be conducted throughout 2008 if deemed necessary.

3. Vegetation Problem Area Plan View

The location of each vegetation problem area is shown on the vegetative problem area plan view included in Appendix A. Each problem area is color coded with yellow for areas of low concern (areas to be watched) or red for high concern (areas where maintenance is warranted).

4. Stem Counts

A summary of the stem count data for each species arranged by plot is shown in Table VIII. This data was compiled from the information collected on each plot using the *CVS-EEP Protocol for Recording Vegetation, Version 4.0*.

The average stem density for the entire site just meets the minimum criteria of 320 stems per acre after three years. However, fourteen of the thirty vegetation plots fall below this threshold number. The largest deficit in woody stems is found along Tributary C (Plots 29 and 30). Only one seedling was found in each of these two plots. The remainder of the plots with an insufficient number of stems are scattered throughout the project area.

Because the average density of the entire site fell below the 320 stems per acre threshold in Year 1, remedial plantings were conducted in late April, 2007 to supplement the number of trees along the streams. Approximately 2000 trees were planted at this time, including 500 trees along Tributary C, and 1500 trees along the other reaches. These additional trees brought the average live stem density to 390 stems per acre, meeting the three year threshold of 320 stems per acre. These additional plantings are the reason why many of the species exhibit 100% survival, with greater Year 2 totals than the Year 1 totals.

It is clear that the survival of seedlings is being affected on this site, as many of the remedial plantings did not survive through one growing season. It is likely that the spread of *Sericea lespedeza* throughout much of the project corridor has hindered the growth and survival of woody vegetation. Where present, this species is dominant, providing a thick coverage of growth approximately three feet high through which any species must break in order to receive sunlight or rainfall. After management of this species is conducted in the spring of 2008, as discussed previously, another round of remedial tree plantings will be conducted. These plantings are intended to bring the site back into compliance with the 320 stems per acre minimum, and to replace any trees inadvertently impacted by the herbicide treatments. The plantings will be spread throughout the project corridor, with an emphasis on Tributary C, which has the lowest stem counts, and Tributary B, which is most impacted by *Sericea lespedeza*.

5. Vegetation Plot Photos

Vegetation plot photos are provided in Appendix A.

B. Stream Assessment

1. Hydrologic Criteria

A network of six crest-stage stream gages was installed on each of the project reaches. The locations of the crest-stage stream gages are shown on the monitoring plan view (Figure 2). No bankfull events were documented for this site during the first year of monitoring. Bankfull events were recorded during Year 2, as documented in Table IX.

Table IX. Verification of Bankfull Events			
Date of Data Collection	Date of Occurrence	Method	Photo #
7/18/07	Unknown	Crest gage at Station 5+00 on Tributary B	BF 1
7/18/07	Unknown (3 events)	Crest gage at Station 54+85 on Tributary A (Lower)	BF 2
10/19/07	9/14/07-9/15/07*	Crest gage at Station 113+37 on Tributary A (Upper)	BF 3

*Date is approximate; based on a review of recorded rainfall data

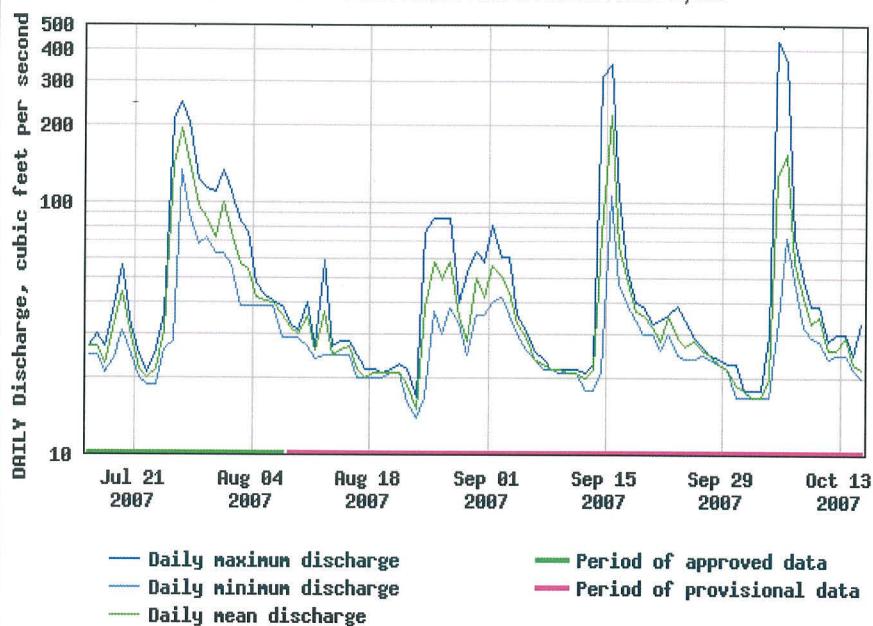

The height of the bankfull event was not measured for the crest gage on Tributary B. The crest gage on Tributary A (Lower) showed evidence of at least 3 separate events, with levels of 16.75, 24.75, and 33.25 inches above bankfull. In October 2007, the crest gage on Tributary A (Upper) registered a bankfull event at a level of 1.24 feet above bankfull elevation. Photographs of the crest gages are shown in Appendix B.

The most likely date for the bankfull event between the July and October readings was after the September 14, 2007 rain event. On this date, rainfall as recorded in Morganton, NC totaled 1.47 inches. As this was the only precipitation event of significance during the preceding three months, this is likely the bankfull event recorded by the crest gage read on October 19, 2007. This corresponds to a high discharge event on September 15, as recorded at USGS Gage 02138500 at Nebo, NC, which lies approximately 15 miles west of Morganton and 5 miles east of Marion, NC. The discharge and gage height recorded at the Nebo station are shown on the hydrographs below.

2. Stream Problem Areas

A summary of the areas of concern identified during the visual assessment of the stream for each year of monitoring is included in Tables Xa and Xb.

Table Xa. Stream Problem Areas – Year 1
South Muddy Creek Tributaries Restoration / EEP Project No. D04006-01

Feature Issue	Station Numbers	Suspected Cause	Photo Number
Aggradation	4+50 (A2)	Large bar, 25 feet aggraded	SPA 1 (Year 1 Report)
	3+00 (A2)	Overwidened channel, 40 feet aggraded	
Bank failure	79+50 (A Middle)	Mat failed; scour hole, 5'	SPA 2, SPA 3 (Year 1 Report)
	12+10 (B)	Complete loss of riffle, bank failure.	
Bank scour	103+00 (A Upper)	Large hole, scour (15 feet)	SPA 4, SPA 5, SPA 6 (Year 1 Report)
	83+30 (A Middle)	Sloughing, coir log undercut and fallen into pool (15 feet)	
	82+70 (A Middle)	Sloughing, coir log undercut and fallen into pool (15 feet)	
	3+00 (A Lower)	Sloughing	
	19+70 (B)	Bank scour around log sill	
	18+50 (B)	Scour at outside meander bend; significant aggradation	
	16+00 (B)	Scour, matting loose and failing, bank slough	
	15+70 (C)	Bank scour/ sloughing	
	4+50 (C)	Bank scour/ sloughing	

Table Xb. Stream Problem Areas – Year 2
South Muddy Creek Tributaries Restoration / EEP Project No. D04006-01

Feature Issue	Station Numbers	Suspected Cause	Photo Number
Bank failure	12+10 (B)	Complete loss of riffle, bank recovering as a result of thick vegetation.	SPA 1
Bank scour	85+64 (A Middle)	Minor bank erosion	SPA 2
	15+70 (C)	Bank scour/ sloughing	
	4+50 (C)	Bank scour/ sloughing; heavily vegetated and stable	

Some unstable areas were found along South Muddy Tributaries in Year 2, including areas of aggradation and bank scour as noted in Table X. Aggradation problem areas noted during Year 1 on Tributary A2 are no longer present. The vegetation along this reach is extremely robust. Lateral bars found during the previous year are no longer present. The Upper and Lower sections of Tributary A had one area of bank scour at approximate profile stations 103+00 and 3+00, respectively. Robust vegetation at both locations is preventing exacerbation as the banks are healing and returning to a stable state. Tributaries B and C and the Middle section of Tributary A each had some areas of bank scour and/or bank erosion. With the exception of minimal bank scour observed during Year 2 at station 85+64 on Tributary Middle A, these areas are now heavily vegetated and stable. Two areas of bank scour along Tributary B and one area of bank failure along the Middle section of Tributary A, were repaired between Year 1 and Year 2. These repairs have been effective, with no anticipated need for further work.

Vegetation along Tributary B is very dense in the downstream reach, covering the stream banks and the streambed itself. The thick vegetation has increased bed roughness, slowing bankfull velocity, and in turn provides optimal conditions for new vegetation to continue to flourish in the channel; however, much of this vegetation is comprised of the invasive *Sericea lespedeza*, discussed under the Vegetation Problem Areas.

3. Stream Problem Areas Plan View

The locations of problem areas are shown on the stream problem area plan view included in Appendix B. Each problem area is color coded with yellow for areas of low concern (areas to be watched) or red for high concern (areas where maintenance is warranted).

4. Stream Problem Areas Photos

Photographs of the stream problem areas are included in Appendix B.

5. Fixed Station Photos

Photographs were taken at each established photograph station on October 23, 2007. These photographs are provided in Appendix B.

6. Stability Assessment Table

The visual stream assessment was performed to determine the percentage of stream features that remain in a stable state after the first year of monitoring. A summary of the assessment for each reach is included in Table XIa through Table XIf. This summary was compiled from the more comprehensive Table B1, included in Appendix B. Only those structures included in the as-built survey were assessed during monitoring and reported in the tables.

* The percentages for Year 1 were updated, using the percentages derived from Table B1 in Appendix B, using the Feature Performance Mean percentages located in the last column of Table B1. The Feature Performance Mean percentages were used for Year 2; therefore, the percentages are now comparable across the years.

¹The tables were completed to include a percentage of stability for pool and riffle features using the definitions provided below for the stream reaches along Tributary A.

Riffle: A portion of the linear stream segment located between two consecutive meander bends.

Pool: A portion of the curvilinear stream segment located in each meander bend.

²Those features not included in the stream restoration were labeled N/A. This includes features such as vanes, J-hooks, rootwads and boulders.

The only category that included unstable features for Tributaries Upper A, Middle A, Lower A and C were meanders, where minor erosion occurred along the outer bends. However, the meanders that had been in a state of degradation have improved during Year 2 due to the increased vegetative cover and associated root mass along the stream corridors. As the vegetation matures, the root mass is expanding both in size, depth and density, enhancing streambank stability. The areas along Tributary A2 with unstable features in Year 1 were locations of aggradation and bar formation in the riffles. These were no longer considered problem areas in Year 2, as the vegetation cover increased along this reach and areas of aggradation noted during Year 1 are no longer evident.

The unstable features on Tributary B were erosion along meander bends and bank scouring around riffles. The overall percentage of stability improved from Year 1 to Year 2, indicating a trend in increased channel stability over time. As discussed previously, the lower reach of Tributary B has become heavily vegetated, increasing bank and streambed stability. Log sills are functioning, maintaining grade control, providing aeration and enhancing aquatic habitat features.

7. Quantitative Measures

Graphic interpretations of cross-sections, profiles and pebble counts are provided in Appendix B. A summary of the baseline morphology for the site is included in Table XII for comparison with the monitoring data shown in the tables in the appendix.

The data provided in Table XII for Year 1 reflects data from only the long-term monitoring reaches assessed along the Year 1 longitudinal profiles, while the As-Built data was collected for the entire reach on each tributary. The stream pattern data provided for Year 1 and Year 2 is the same as the data provided from the As-Built survey, as pattern has not changed based on Year 1 and Year 2 stream surveys and visual field assessment of the each of the reaches in their entirety.

Bedform features continue to evolve along the restored reaches as shown on the long-term longitudinal profiles. Riffle lengths and slopes are stable. Pool to pool spacings are representative of reference reach conditions, adjusted for drainage area and bankfull width. The pools have developed glide features, providing spawning habitat for native fishes and riffle substrates conducive to benthic macro-invertebrate populations to re-emerge. Of interest, is the change (median decrease) in pool to pool spacings between Year 1 and Year 2 on Upper Tributary A and to a lesser degree on the other long-term monitoring profiles. This bedform adjustment may be attributed to extended drought during the summer of 2007 (low flow conditions) and minimal flushing of sand-sized particles through the project reaches. Future monitoring may confirm this hypothesis. Comparison of As-Built, Year 1 and Year 2 long-term stream monitoring show successive increases in channel-floodplain connectivity and increasingly stable channel dimensions, interpreted from width/depth ratios, entrenchment ratios, bank height ratios, etc. as shown on the long-term monitoring cross-sections. Median particle sizes of the stream channels ranged from fine to coarse gravel in the riffle/run areas, and silt to medium sand in the pool/glide areas. Remedial maintenance work on the restored reaches is not planned at this time.

³ As-Built dimension data includes each riffle cross-sections in a described reach.

Monitoring Year 1 thru 5 data is derived by EMH&T from the long-term profile reach only

Note: Where only two measurements were taken, they are listed as 'Min' and 'Max' values with no 'Med' value;
where only one measurement was taken, that is listed as a 'Med' value.

Blank fields indicate either no measurement was taken or data were not available at the time of this report.

IV. METHODOLOGY

Year 1 vegetation monitoring was conducted in September 2006 using the *CVS-EEP Protocol for Recording Vegetation, Version 4.0* (Lee, M.T., Peet, RK., Roberts, S.R., Wentworth, T.R. 2006). Year 2 vegetation monitoring was conducted in September 2007 using the same protocol. Year 1 stream monitoring was conducted in April 2007 to provide adequate time between the as-built survey (accepted in January 2007) and the Year 1 monitoring survey. Stream monitoring for Year 2 occurred in October 2007, to provide six months between the Year 1 and Year 2 surveys. Subsequent stream monitoring will occur in the fall of Years 3, 4 and 5 to provide a full year between surveys. Vegetation monitoring will continue to be conducted in the fall of each subsequent year of monitoring, providing a full year between vegetative surveys.

APPENDIX A
Vegetation Raw Data

1. Vegetation Problem Area Photos
2. Vegetation Problem Area Plan View
3. Vegetation Monitoring Plot Photos
4. Vegetation Data Tables

VPA 1

Overview of the spread of *Sericea lespedeza* in the stream valley along Tributary A (lower), looking downstream from station 19+00.

(EMH&T, Inc. 10/23/07)

VPA 2

View of *Sericea lespedeza* growing along bank of Tributary A (middle) near station 85+64.

(EMH&T, Inc. 10/23/07)

Table 1. Vegetation Metadata

Report Prepared By	Holly Blunck
Date Prepared	11/14/2007 8:16
database name	CVS_EEP_DataEntry_v202.mdb
database location	Q:\ENVIRONMENTAL\Monitoring\EEP Vegetation Database
DESCRIPTION OF WORKSHEETS IN THIS DOCUMENT -----	
Metadata	This worksheet, which is a summary of the project and the project data.
Plots	List of plots surveyed.
Vigor	Frequency distribution of vigor classes.
Vigor by Spp	Frequency distribution of vigor classes listed by species.
Damage	List of most frequent damage classes with number of occurrences and percent of total stems impacted by each.
Damage by Spp	Damage values tallied by type for each species.
Damage by Plot	Damage values tallied by type for each plot.
Stem Count by Plot and Spp	Count of living stems of each species for each plot; dead and missing stems are excluded.
PROJECT SUMMARY-----	
Project Code	D0400601
project Name	South Muddy Creek
Description	Restoration of tributaries A, A2, B and C of South Muddy Creek
length (ft)	
stream-to-edge width (ft)	
area (sq m)	
Required Plots (calculated)	
Sampled Plots	30

Table 2. Vegetation Vigor by Species

Species	4	3	2	1	0	Missing
<i>Alnus serrulata</i>	13	3				14
<i>Cephalanthus occidentalis</i>	5					
<i>Cornus amomum</i>	54	11	2			3
<i>Fraxinus pennsylvanica</i>	54	11	3	1		1

TRIBUTARY A-UPPER

Date: December, 2007

Job No. 2006-1627

Scale: 1" = 500'

See Appendix B-5

SPA 1

Bank failure along Tributary B at station 12+10. Buffer vegetation is obscuring the erosion.
(EMH&T, Inc. 10/23/07)

SPA 2

Bank scour along Tributary C at station 15+70.
(EMH&T, Inc. 10/23/07)

Fixed Station 1
Overview of Tributary A (upper), facing upstream.
(EMH&T, Inc. 10/23/07)

Fixed Station 2
Overview of valley along confluence of Tributary A2 with Tributary A, facing upstream.
(EMH&T, Inc. 10/23/07)

Fixed Station 3

Overview of valley along Tributary A (lower) near station 31+50, facing downstream.
(EMH&T, Inc. 10/23/07)

Fixed Station 4

Overview of valley along Tributary A (lower) near station 31+50, facing upstream.
(EMH&T, Inc. 10/23/07)

Fixed Station 5

Overview of valley on Tributary A (lower) at large culvert, facing upstream.
(EMH&T, Inc. 10/23/07)

Fixed Station 6

Overview of valley on Tributary A (lower) at large culvert, facing downstream.
(EMH&T, Inc. 10/23/07)

Fixed Station 7
Overview of valley along Tributary B, facing upstream.
(EMH&T, Inc. 10/23/07)

Fixed Station 8
Overview of valley along Tributary B, facing downstream.
(EMH&T, Inc. 10/23/07)

Fixed Station 9

**Overview of valley along Tributary C near station 6+50, facing downstream.
(EMH&T, Inc. 10/23/07)**

Fixed Station 10

**Overview of valley along Tributary C near station 8+60, facing downstream.
(EMH&T, Inc. 10/23/07)**

Table B1. Visual Morphological Stability Assessment
South Muddy Creek Tributaries Restoration / EEP Project No. D04006-01

Feature Category	Metric (per As-built and reference baselines)	Segment/Reach: A (upper)			% Perform. in Stable Condition	Feature Perform. Mean or Total
		(# Stable) Number Performing as Intended	Total number per state As-built	Total Number / feet in unstable state
