1.0 EXECUTIVE SUMMARY

The Tate Farm (Ripshin Branch) Stream and Wetland Restoration Site (hereafter referred to as the Site) is situated within US Geological Survey (USGS) hydrologic unit 05050001 of the Upper New River Basin and is in a portion of NC Division of Water Quality (NCDWQ) Priority Sub-basin 05-07-02. The project is located in the northwest corner of Ashe County, about 1 mile south of the Virginia state line and 3 miles east of the Tennessee state line (Figure 1, Appendix A). The Site is encompassed within a 61.92-acre easement located in a tract owned by Michael and Virginia Tate. The Site includes an unnamed tributary to Ripshin Branch (UT), Ripshin Branch proper, associated floodplain wetlands, and additional tributaries found on the property (Figure 2, Appendix B). This report (compiled based on EEP's *Procedural Guidance and Content Requirements for EEP Monitoring Reports,* Version 1.4, dated 11/7/11) summarizes data for Year 3 (2014) monitoring.

The project goals are as follows.

- Improve stream water quality and ecological function by excluding livestock, restoring pool and riffle sequences, and restoring tree canopy and instream large woody debris.
- Enhance aquatic and terrestrial habitat in the stream corridor and adjacent wetlands.
- Enhance and/or restore the ecological function of riparian wetlands.
- Restore the riparian corridor (forested buffer) for watershed and wildlife benefits.
- Enhance habitat for native brook trout (*Salvelinus fontinalis*) and improve fishery potential.
- Increase biodiversity of the stream ecology, riparian buffers, and wetlands.

These goals will be accomplished through the implementation of the following objectives.

- Improve channel geomorphology toward reference conditions by providing watershed scaled and Rosgen-typed channel dimension, adding floodplain benches where floodplain access is not feasible, restoring sinuous pattern to straightened reaches where possible, and adjusting profile as needed to restore or maintain sediment transport equilibrium.
- Restore stream-side floodprone area where appropriate (increase floodwater access to the floodplain).
- Reduce sediment and nutrient loading by reshaping and stabilizing banks, reducing bank scour, excluding livestock, and restoring riparian buffers.
- Enhance or restore wetland hydrology and vegetation in former pastures and filled wetlands.

After construction, five vegetation plots were established and sampled. During Year 2 (2013) monitoring, thirteen additional vegetation plots were established and sampled. Vegetation Success Criteria (from the approved *Ripshin Branch Stream & Wetland Restoration Plan* [NCEEP 2007]) include the following.

- Survival of planted vegetation should exceed 80 percent after 5 years following planting (minimum 260 stems/acre).
- Planted vegetation stabilizing at 20 years with distinct canopy, subcanopy, and shrub layers.
- Establishment of herbaceous cover over 75 percent of the soil surface in restored wetlands and riparian areas.
- Plant biodiversity dominated by native species, with minimal ecological impact from invasive species.

Overall, vegetation was slightly below success criteria with an average of 286 planted stems/acre (excluding livestakes) across the Site. In addition, six of the eighteen vegetation monitoring plots met, or exceeded success criteria of 320 stems/acre (minimum stem count after 2 years). Vegetation plots 2 and 4 were below success criteria with 283 and 162 stems/acre, respectively. Potential causes of the low stem counts at these plots include excessive hydrology associated with wetland restoration and over competition by sedges and soft rush (*Carex* spp. and *Juncus effusus*, respectively). Additional plots below success criteria can be attributed to poor planted stem survival due to harsh, high elevation climate and poor soils. Supplemental planting throughout these areas is recommended for the winter of 2014/2015.

In addition to low stem densities, one vegetation area of concern was noted at the beginning of 2013. An overbank event scoured the floodplain and deposited gravel and silt along both banks at the downstream end of Ripshin Branch near Vegetation Plot 5, and a number of planted stems were buried by debris and sediment. This area appears to have stabilized, with woody stems reestablishing. However, it is still scoured and is characterized by poorly developed rocky soils.

A visual assessment and geomorphic survey were completed for the Site. The visual assessment indicated that project reaches were performing within established success criteria ranges as shown below. During a 2013 heavy, summer rain event, a boulder was dislodged in a right bank structure in the lower portion of Ripshin Branch. The boulder has since been stabilized by dense herbaceous vegetation and is no longer dislodged. The structure will continue to be monitored closely but is not expected to dislodge again during normal rain conditions.

During Monitoring Years 2 and 3 (2013-2014), approximately 25,320 linear feet of additional stream was mapped onsite using sub-meter GPS. The locations of additional streams are depicted on Figures 2A-2F (Appendix B).

Stream Success Criteria (from the approved *Ripshin Branch Stream & Wetland Restoration Plan* [NCEEP 2007]) is as follows.

- Channel morphology retains the design stream type over the majority of the reach.
- Coarsening of riffle bed material in newly constructed reaches.
- Pool/riffle spacing should remain fairly constant.
- Maintenance of bankfull width at riffles within 10 percent of the design.
- Maintenance of bank height ratios at 1:1.
- Bank stability over 90 percent of altered channel reaches.
- Dimension and profile stability over 90 percent of altered channel reaches.
- No significant channel aggradation or degradation.
- Minimal development of instream bars.
- Biological populations (invertebrate and fish) remain constant or increase and species composition indicates a positive trend.
-

Success criteria for stream restoration will be based on stream stability assessed using measurements of stream dimension, pattern, and profile; Site photographs; visual assessments; and vegetation sampling. Stream appear to be functioning properly, emulates design conditions, and is trending towards success.

Wetland hydrology success criteria (from the approved *Ripshin Branch Stream & Wetland Restoration Plan* [NCEEP 2007]) is as follows.

- Hydrologic monitoring indicates groundwater within 12 inches of the ground surface for 10 percent of the growing season
- Increasing wetland vegetation
- Development of hydric soils
- Fulfill US Army Corps of Engineers (USACE) criteria for jurisdictional wetlands

Six groundwater gauges were installed at the Site in mid-October 2012; therefore, no groundwater gauge data is available for year 1 (2012) monitoring. Five of six groundwater gauges were saturated/inundated for well over 10 percent of the year 3 (2014) growing season. Groundwater Gauge 4 fell just short of success, being inundated 8 percent of the growing season. A battery failure at the beginning of the growing season resulted in a loss of data. The gauge was replaced and is currently functioning properly, but during a subsequent visit additional data was lost due to a failed Meazura PDA. Based on hydrology of the additional gauges, in addition to abundant precipitation, it is likely that Gauge 4 would have met success during the 2014 growing season.

Summary information/data related to the occurrence of items such as beaver or encroachment and statistics related to performance of various project and monitoring elements can be found in tables and figures within this report's appendices. Narrative background and supporting information formerly found in these reports can be found in the Baseline Monitoring Report (formerly Mitigation Plan) and in the Mitigation Plan (formerly the Restoration Plan) documents available on the NC Ecosystem Enhancement Program (NCEEP) website. All raw data supporting the tables and figures in the appendices are available from NCEEP upon request.

2.0 METHODOLOGY

2.1 Vegetation Assessment

Five vegetation plots were established and marked during the Year 1 (2012) monitoring period, and 13 additional plots were established and marked during the Year 2 (2013) monitoring period, yielding a total of 18 vegetation plots on the site. Plots were established by installing 4-foot, metal U-bar post at the corners and a 10-foot, 0.75 inch PVC at the origin. The plots are 10 meters square or 20 meters by 5 meters and are located randomly within the Site. These plots were surveyed in July 2014 for the Year 3 (2014) monitoring season *CVS-EEP Protocol for Recording Vegetation, Levels 1-2 Plot Sampling Only Version 4.2* (Lee et al. 2008) (http://cvs.bio.unc.edu/methods.htm); results are included in Appendix C. The taxonomic standard for vegetation used for this document was *Flora of the Southern and Mid-Atlantic States* (Weakley 2012).

2.2 Stream Assessment

Annual stream monitoring was conducted in May 2014. Measurements were taken using a Topcon GTS 303 total station and Recon data collector. The raw total station file was processed using Carlson Survey Software into a Computer Aided Design (CAD) file. Coordinates were

exported as a text/ASCII file to Microsoft Excel for processing and presentation of data. Pebble counts were completed using the modified Wolman method (Rosgen 1993).

Eight permanent cross-sections, six riffle and two pool, were established and will be used to evaluate stream dimension; locations are depicted on Figures 2A and 2B (Appendix B). Cross-sections are permanently monumented with 4-foot metal U-bar posts at each end point. Cross-sections will be surveyed to provide a detailed measurement of the stream and banks, including points on the adjacent floodplain, top of bank, bankfull, breaks in slope, edge of water, and thalweg. Data will be used to calculate width-depth ratios, entrenchment ratios, and bank height ratios for each cross-section. In addition, pebble counts were completed at cross-sections 4 and 8, and photographs will be taken at each permanent cross-section annually.

Two monitoring reaches were established (Unnamed Tributary and Ripshin Branch) and will be used to evaluate stream pattern and longitudinal profile; locations are depicted on Figures 2A and 2B (Appendix B). Longitudinal profile measurements include average water surface slopes, facet slopes, and pool-to-pool spacing. Seventeen permanent photo points were established throughout the restoration reach; locations are depicted on Figures 2A and 2B (Appendix B). In addition, visual stream morphology and stability assessments were completed in each of the two monitoring reaches to assess the channel bed, banks, and in-stream structures.

			Total	2	8.22	47.0%
3. Areas of Poor Growth Rates or Vigor	Areas with woody stems of a size class that are obviously small given the monitoring year.	0.25 acres	NA	0	0.00	0.0%
			Cumulative Total	2	8.22	47.0%

Easement Acreage[2] **61.9**

Vegetation Category	Definitions	Mapping Threshold	CCPV Depiction	Number of Polygons	Combined Acreage	% of Easement Acreage
4. Invasive Areas of Concern[4]	Areas or points (if too small to render as polygons at map scale).	100 SF	NA	0	0.00	0.0%
5. Easement Encroachment Areas[3]	Areas or points (if too small to render as polygons at map scale).	none	NA	0	0.00	0.0%

1 = Enter the planted acreage within the easement. This number is calculated as the easement acreage minus any existing mature tree stands that were not subject to supplemental planting of the understory, the channel acreage, crossings or any other elements not directly planted as part of the project effort.

2 = The acreage within the easement boundaries.

3 = Encroachment may occur within or outside of planted areas and will therefore be calculated against the overall easement acreage. In the event a polygon is cataloged into items 1, 2 or 3 in the table and is the result of encroachment, the associated acreage should be tallied in the relevant item (i.e., item 1,2 or 3) as well as a parallel tally in item 5.

4 = Invasives may occur in or out of planted areas, but still within the easement and will therefore be calculated against the overall easement acreage. Invasives of concern/interest are listed below. The list of high concern spcies are those with the potential to directly outcompete native, young, woody stems in the short-term (e.g. monitoring period or shortly thereafter) or affect the community structure for existing, more established tree/shrub stands over timeframes that are slightly longer (e.g. 1-2 decades). The low/moderate concern group are those species that generally do not have this capacity over the timeframes discussed and therefore are not expected to be mapped with regularity, but can be mapped, if in the judgement of the observer their coverage, density or distribution is suppressing the viability, density, or growth of planted woody stems. Decisions as to whether remediation will be needed are based on the integration of risk factors by EEP such as species present, their coverage, distribution relative to native biomass, and the practicality of treatment. For example, even modest amounts of Kudzu or Japanese Knotweed early in the projects history will warrant control, but potentially large coverages of Microstegium in the herb layer will not likley trigger control because of the limited capacities to impact tree/shrub layers within the timeframes discussed and the potential impacts of treating extensive amounts of ground cover. Those species with the "watch list" designator in gray shade are of interest as well, but have yet to be observed across the state with any frequency. Those in *red italics* are of particular interest given their extreme risk/threat level for mapping as points where isolated specimens are found, particularly ealry in a projects monitoring history. However, areas of discreet, dense patches will of course be mapped as polygons. The symbology scheme below was one that was found to be helpful for symbolzing invasives polygons, particulalry for situations where the conditon for an area is somewhere between isolated specimens and dense, discreet patches. In any case, the point or polygon/area feature can be symbolized to describe things like high or low concern and species can be listed as a map inset, in legend items if the number of species are limited or in the narrative section of the executive summary.

Report Prepared By	Corri Faquin
Date Prepared	7/31/2014 15:22
database name	Axiom-EEP-2014-A-v2.3.1.mdb
database location	\\AE-SBS\RedirectedFolders\KJernigan\Desktop
computer name	KEENAN-PC
file size	68812800
DESCRIPTION OF WORKSHEETS IN THIS DOCUMENT----------	
Metadata	Description of database file, the report worksheets, and a summary of project(s) and project data.
Proj, planted	Each project is listed with its PLANTED stems per acre, for each year. This excludes live stakes.
Proj, total stems	Each project is listed with its TOTAL stems per acre, for each year. This includes live stakes, all planted stems, and all natural/volunteer stems.
Plots	List of plots surveyed with location and summary data (live stems, dead stems, missing, etc.).
Vigor	Frequency distribution of vigor classes for stems for all plots.
Vigor by Spp	Frequency distribution of vigor classes listed by species.
Damage	List of most frequent damage classes with number of occurrences and percent of total stems impacted by each.
Damage by Spp	Damage values tallied by type for each species.
Damage by Plot	Damage values tallied by type for each plot.
Planted Stems by Plot and Spp	A matrix of the count of PLANTED living stems of each species for each plot; dead and missing stems are excluded.
ALL Stems by Plot and spp	A matrix of the count of total living stems of each species (planted and natural volunteers combined) for each plot; dead and missing stems are excluded.
PROJECT SUMMARY----------	
Project Code	372
project Name	Tate Farm
Description	Stream and Wetland Restoration
River Basin	New
length(ft)	
stream-to-edge width (ft)	
area (sq m)	
Required Plots (calculated)	
Sampled Plots	18

HYDROLOGY DATA

Table 12. Verification of Bankfull Events

Table 13. Wetland Hydrology Criteria Attainment Summary

Groundwater Gauge Graphs

Table 12. Verification of Bankfull Events

Tate Farm (Ripshin Branch) Stream and Wetland Restoration Site (EEP Project Number 372)

Date of Data Collection	Date of Occurrence	Method	Photo (if available)
June 7, 2013	January 17, 2013	Approximately 3.9 inches of rain documented* at a nearby rain station over a four day period from January 14-17, 2013.	---
April 28, 2013	January 30, 2013	Wrack and sediment observe on top of banks after approximately 4.2 inches of rain was documented* at a nearby rain station on January 30, 2013.	1-3
June 12, 2013	May 7, 2013	Approximately 4.34 inches of rain documented over three days at the onsite rain gauge.	---
June 12, 2013	May 24, 2013	Wrack observed in the floodplain after approximately 5.92 inches of rain was documented over eight days at the onsite rain gauge.	4
August 13, 2013	July 4, 2013	Approximately 4.13 inches of rain documented over two days at the onsite rain gauge.	---
August 13, 2013	August 10, 2013	Wrack and laid back vegetation observed in the flood plain after approximately 3.52 inches of rain was documented at the onsite rain gauge.	5
October 7, 2014	September 2-8, 2014	Wrack observed in floodplain after rainfall totaling 4.37 inches documented at the onsite rain gauge.	6

Table 13. Wetland Hydrology Criteria Attainment Summary

Tate Farm (Ripshin Branch) Stream and Wetland Restoration Site (EEP Project Number 372)

Gauge	Success Criteria Achieved/Max Consecutive Days During Growing Season (Percentage)				
	Year 1 (2012)*	Year 2 (2013)	Year 3 (2014)	Year 4 (2015)	Year 5 (2016)
1	--	130 Days (81%)	34 Days (21%)		
2	--	160 Days (100%)	160 Days (100%)		
3	--	160 Days (100%)	160 Days (100%)		
4	--	152 Days (95%)	14 Days** (8%)		
5	--	160 Days (100%)	47 Days (29%)		
6	--	160 Days (100%)	46 Days (26%)		

* Groundwater Gauges were installed in October 2012; therefore, groundwater monitoring was initiated during the Year 2 (2013) monitoring year.

**Gauge 4 malfunctioned at beginning of 2014 growing season resulting in loss of data. A battery failure at the beginning of the growing season resulted in a loss of data. The gauge was replaced and is currently functioning properly, but during a subsequent visit additional data was lost due to a failed Meazura PDA. Based on hydrology of the additional gauges, in addition to abundant precipitation, it is likely that Gauge 4 would have met success for year 3 (2014).
