I. Executive Summary/Project Abstract

The Tick Creek stream restoration and preservation project is located southeast of Siler City, in Chatham County, North Carolina, southeast of the intersection of Rives Chapel Church Road and Jim Moody Road. The project design was completed by the North Carolina Department of Transportation (NCDOT) in 2002, and includes preservation of a 114 foot wide buffer along 3,733 feet of Tick creek (immediately downstream of the Rives Chapel Church Road Bridge), and restoration of 2,597 feet of an unnamed tributary to Tick Creek (UT). The entire project occupies 29 contiguous acres in USGS HUC 03030003070023 (NCDWQ Cape Fear River Subbasin 03-06-12). According to telephone conversations with Jamie Lancaster, PE (construction project manager, NCDOT), construction was completed on the Tick Creek site on 1 September 2005 and bare rootstock planting was completed during the week of 6 February 2006.

As-built qualitative evaluation was conducted by RJG&A during early February 2006. The First Annual Monitoring Report (2006) indicated that the project had met its geomorphologic and vegetation goals design by October 2007. The last 2006 visit to the Tick Creek site was on 1 November. No on-site evidence of bankfull events was observed during 2006.

The 2007 evaluation and monitoring of the Tick Creek stream restoration site indicates that the project has met all its design goals during the second year post-construction. As stated below, evidence of bankfull flow was observed during the April 2007 evaluation.

USGS hydrograph data indicate that at least one bankfull event was likely to have occurred during December 2006. At least one other was likely to have occurred during spring 2007. The project, therefore, has met its bankfull goals for two consecutive years.

For the second consecutive year average planted woody stem density (890 per acre) has exceeded the vegetation restoration goal.

II. Project Background

2.1. Project Objectives

The Tick Creek Stream Restoration Project was designed to achieve the following objectives:

- restore pre-agricultural water quality,
- improve aquatic habitat function and value,
- improve sediment transport capability,
- restore bank stability.

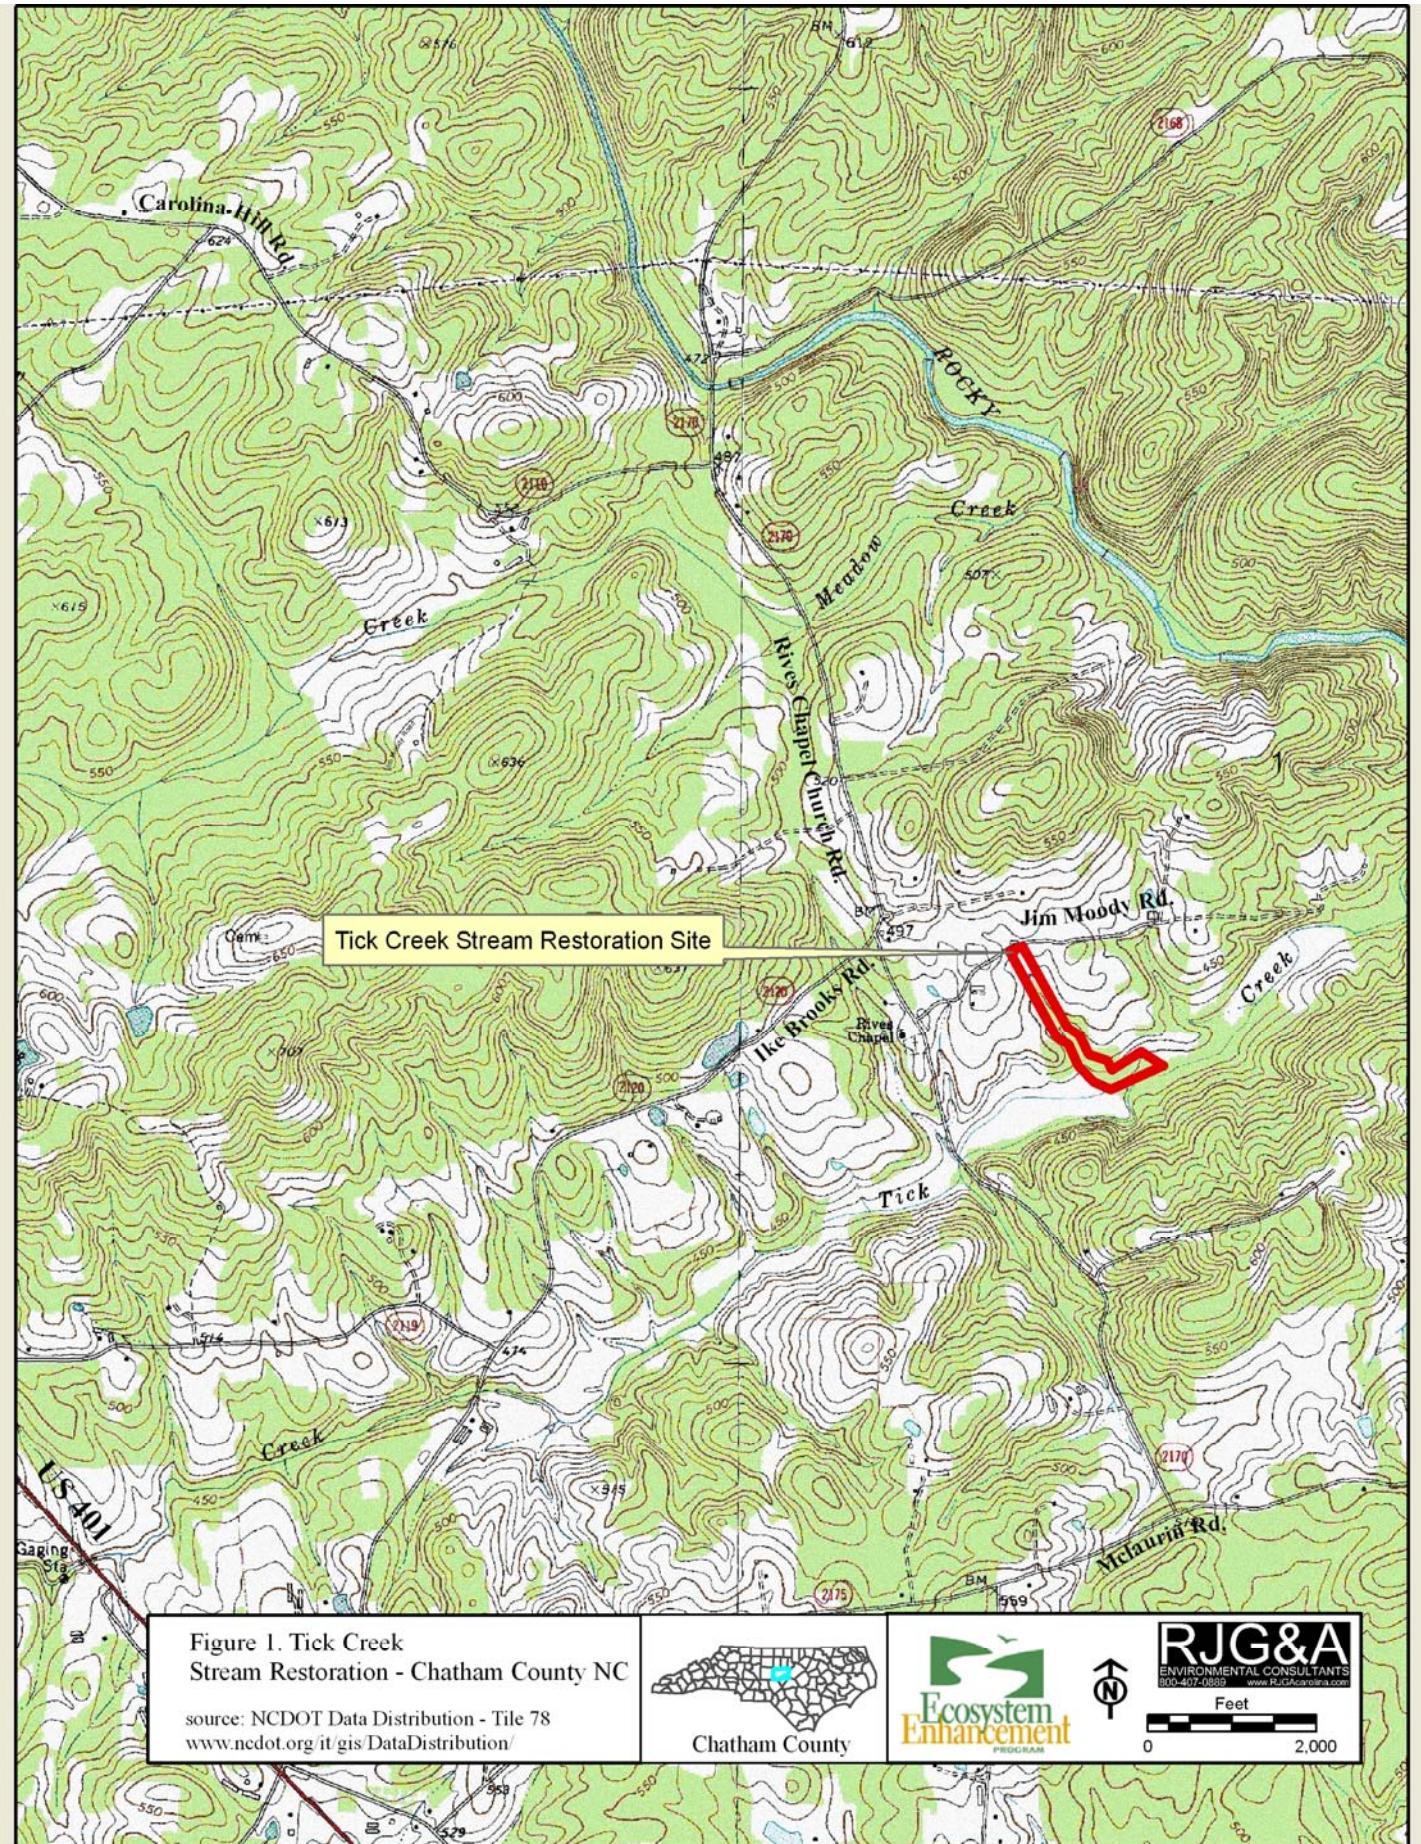

2.1. Project Objectives

The Tick Creek Stream Restoration Project involved the preservation of 3,733 linear feet of Tick Creek and a Priority I restoration of 2,946 linear feet of an unnamed tributary that flows into Tick Creek. The project involved bedform transformations, channel dimension adjustments, pattern alterations, structure installation (root wads, rock vanes, and woody debris), and riparian buffer restoration (woody vegetation planting and stock exclusion).

2.3. Location and Setting

To get to the Tick Creek restoration site from U.S. 64, turn south on Rives Chapel Church Road (~0.9 mile east of Siler City), travel 4.4 miles, turn left (east) onto Jim Moody Road. The upstream boundary of the unnamed tributary restoration site is 0.3 miles east of the intersection, on the right (south) side of the road. The project's western easement boundary (preservation) begins on the downstream side of the Rives Chapel Church Road Bridge over Tick Creek (south of the Jim Moody Rd. intersection) (Figure 1).

The 2002 Tick Creek Restoration Plan describes the site's pre-restoration land use as cattle pasture that involved agricultural clearing, stream ditching and straitening, and unrestricted cattle access to the stream. This land use caused bank instability, which increased sediment load. This caused the direct loss of aquatic habitat and caused the impairment and degradation of aquatic resources along the restoration project's entire reach (from the Jim Moody Road culvert, to the confluence with Tick Creek).

2.4. History and Background

The project design was completed by the North Carolina Department of Transportation (NCDOT) in 2002, and includes preservation of a 114 foot wide buffer along 3,733 feet of Tick creek and restoration of 2,597 feet of an unnamed tributary to Tick Creek (UT). According to telephone conversations with Jamie Lancaster, PE (construction project manager, NCDOT), construction was completed on the Tick Creek site on 1 September 2005 and bare rootstock planting was completed during the week of 6 February 2006.

III. Project Conditions and Monitoring Results

The first qualitative project evaluation in the second growing season was conducted on 6 April 2007. Second annual quantitative geomorphologic and vegetation data were collected during July 2007. The site was again qualitatively assed on 28 October 2007.

Flowing water was observed in the channel in 2007 only during the April site visit. No water was observed during the July site visit. Pools were full, but no flowing water was observed during the October evaluation.

Several relatively minor geomorphologic problem areas were observed during April 2007. Fewer problem areas were observed in October, but the lack of flow, at the time of the visit and for several months previously, reduced the ability to identify and accurately assess flow patterns.

3.1. Vegetation Assessment

Vegetation monitoring data for Year 2 can be found in Appendix A, Tables 1 through 5. Vegetation plot photos are also in Appendix A.

3.1.1. Vegetation Problem Areas

Overall, planted woody vegetation was successful in 2007. Planted woody stem success was almost triple the required 320 stems, when averaged for all reaches (890.34/acre).

As was observed in Reach 1 in 2006, woody stem planting in the areas furthest from the stream banks was sporadic, minimal, and absent in some places. Because of the lack of overstory from mature trees, which are present in Reach 2 and most of Reach 3, early successional herbaceous volunteer density and relative cover was again high (dog fennel (*Eupatorium capillofolium*), and horseweed (*Conyza canadensis*)). Natural succession of invasive perennials, primarily blackberry (*Rubus argutus*) has begun throughout Reach 1. This type of early sucessional herbaceous density is common in recently disturbed areas and can be beneficial to the planted stems by prolonging soil moisture in upland areas and reducing early evapotranspiration, provided invasive woody species don't also colonize, and the newly planted *understory* of woody stems remains successful, which it has after its second growing season. Invasive woody volunteers were not quantitatively observed in Reach 1's monitoring plot (plot 1). They are relatively sparse outside the plots.

Reach 2 had good success rates for planted individuals, but, invasion from autumn olive (*Eleaganus umbellata*), mimosa (*Albizia julibrissin*), and Chinese and Japanese privet (*Ligustrum sinense* and *L. japonicum*, respectively) appears to have increased since 2006. Similarly, native early-successional woody species density, particularly sweet gum (*Liquidambar styraciflua*), has significantly increased in Reach 2 since 2006. Because of

the abundance of these species in adjacent forests, their successful management within the restoration area may be difficult. Similarly, the invasive herbaceous Chinese lespedeza's (*Lespedeza cuneata*) density has also increased since 2006 in Reach 2, especially where groundwater is closer to the surface (during typical, not record drought, years). The planted woody stem success under these invasive herbaceous stands is relatively high, so, like in 2006, continued observation, without remedial action, is appropriate.

As in 2006, Reach 3 had planted woody stem density well above the targeted 320 stems per acre, and relatively minimal invasive species problems. Invasive individuals were present, but much less dense than in either Reach 1 or Reach 2. A suspected cause of the relatively high mortality inside this large bend is substrate compaction. The Restoration Design Plan View map indicates that a relatively large *staging area* was located here during construction. Because of the adequate live planted stem density in plot 6 no remedial action is recommended at this time. Like in the Reach 1 and Reach 2 problem areas, continued observation is appropriate.

3.1.2. Vegetation Problem Areas

See Figures A1-2 in Appendix A for the Current Conditions Plan View for vegetation.

3.2. Stream Assessment

3.2.1. Procedural Items

3.2.1.1. Morphometric Criteria

RJG&A staff evaluated the condition and success of the Tick Creek Stream Restoration project during April, July, and October 2007. Overall, the site is maintaining its as-built dimension, pattern, and profile, and planted woody stem success is high. During July 2007 the third annual cross section, pattern, and longitudinal profile data were collected based on the 2003 Stream Mitigation Guidelines (USACE 2003). Fifteen cross-sections were surveyed and a longitudinal profile of the entire UT was conducted. Photographs were taken at all cross sections, and at the 14 permanent photo locations (established by NCDOT during February 2006) during the July survey.

3.1.1.2. Hydrologic Criteria

No crest gauges are installed on the Tick Creek site and on-site quantitative hydrologic evaluation is therefore not possible. As reported in the spring 2007 Initial Assessment, on-site qualitative evidence of at least one bankfull event (rake and drift lines and downed vegetation/stems above the bankfull elevation) was observed on 6 April 2007 at several cross vanes and on the inside of meanders below station 1,700. The previous site visit/observation was on 1 November 2006.

The USGS stream gauge on Tick Creek near Mount Vernon Springs (USGS 02101800) is located on Tick Creek, approximately 3 miles upstream from the restoration site's confluence. It has a drainage area of 15.5 square miles. Bankfull discharge at this gauge is 655.3 cubic feet per second (cfs) (Harmen, 1999). Based on USGS data for 2007 (Figure 3), there have been five bankfull events since 1 November 2006 (Figure 3 and Exhibit Table VIII).

Based on the dates of occurrence, the Tick Creek stream restoration site has received at least one bankfull event during both its first and second monitoring years.

Figure 3. USGS Stream gauge data for Tick Creek upstream of US 421 - Tick Creek Stream Restoration - EEP Project #379

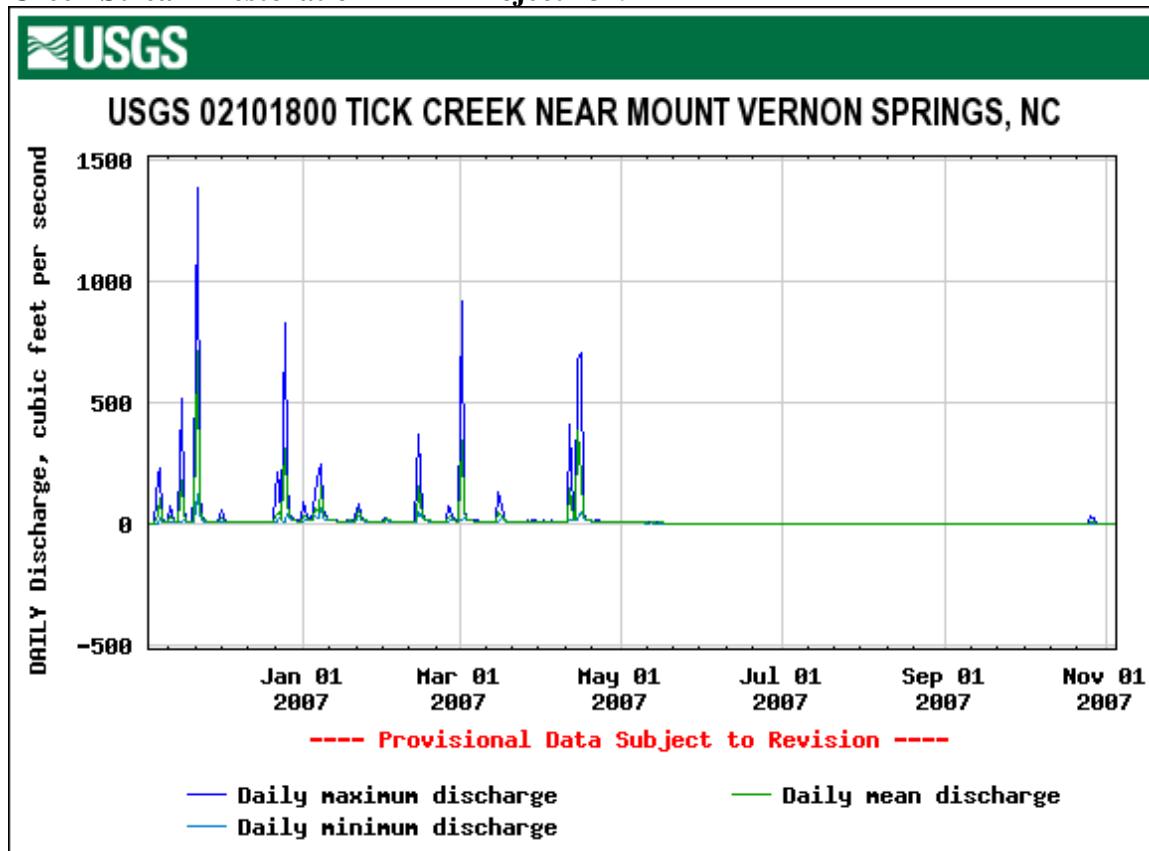

Exhibit Table V. Verification of Bankfull Events – Tick Creek Stream Restoration - EEP Project #379

NA	2 May 2007	Proximal USGS gauge resource	919
NA	15 April 2007	Proximal USGS gauge resource	670
NA	16 April 2007	Proximal USGS gauge resource	704

3.2.1.3. Bank Stability Assessments

A detailed BEHI only applies to Monitoring year 5 and was, therefore, not performed during 2007 (monitoring year 2).

3.2.2. Stream Problem Areas

The quantitative data and qualitative evaluations indicate that the structure and function of the entire restoration project closely match the as built conditions during the second monitoring year, (i.e. little change has occurred)

As shown in Appendix B2, 16 structural and substrate problem areas were identified during the 28 October 2007 qualitative evaluation. Two of these, as illustrated in B1 (Current Conditions Plan View (Streams)), have obviously worsened. They are both located in the final series of step pools above restoration Reach 3's confluence with Tick Creek. They warrant close and frequent observation to prevent them from becoming undermined, which could eliminate grade control.

With the exception of the channel headcut (station 396) and the lateral bank cut between rootwads (station 1203), the remaining 12 problem areas identified had been previously observed. Because of the lack of flowing water inside the restored channel, the condition of five of them (stations 290, 545, 760, and 2,373) was not clear. Several problem areas identified as locations with moderate piping during April 2007 appeared to have stabilized.

No significant aggradation in pools was observed during October 2007. Special attention was given to evaluation of the three pools in Reach 3, and the one in Reach 2 that were cited in the 2007 Initial Assessment and the associated Problem Area Plan View Map 3.2. Since the April 2007 evaluation, all four pools appear to have been scoured during subsequent storm events and are functioning as designed.

3.2.3. Fixed Photo Station Photos

Appendix B4 contains the 16 photo station photos.

IV. Methodology

Monitoring methodologies follow the current EEP-provided templates and guidelines (Lee *et al* 2006). Photographs were taken digitally. A Trimble Geo XT handheld mapping-grade unit was used to collect cross section, vegetation corner, photopoint, and problem area locations. Additional notations were written on the as-built plan sheets.

4.1. Stream Methodology

Methods employed were a combination those specified in the Mitigation Plan, the First Annual Monitoring Report, and standard regulatory guidance and procedures documents. Stream monitoring data was collected using the techniques described in US ACE Stream Mitigation Guidelines, US Forest Service's Stream Channel Reference Sites, and Applied River morphology (USACE, 2003; Harrelson et al., 1994; Rosgen, 1996). A South Total Station and Nikon automatic level were used for collecting all geomorphic data. Photographs facing downstream were taken at each cross section.

4.2. Vegetation Methodology

Eight representative vegetation survey plots were selected and installed in reaches 1, 2, and 3 during September 2006, pursuant to the EEP/CVS vegetation monitoring protocol (Lee *et al* 2006). All plots measure 100 square meters and are either 10 meters by 10 meters, or five meters by 20 meters. Pursuant to the guidelines, the four corners of each plot (0,0; 0,10; 10,0; and 10,10) were marked with 18 inch long one half inch diameter galvanized steel conduit.

Level 1 (planted woody stems) and Level 2 (volunteer woody stems) data collection was performed in all plots, pursuant to the most recent CVS/EEP protocol (Lee *et al* 2006). Within each plot, each planted woody stem location (x and y) was recorded, and height and live stem diameter were recorded for each stem location. All planted stems were identified with pink flagging. Vegetation was identified using Weakley (Weakley 2007). Photos were taken of each vegetation plot from the 0,0 corner.

Tables 1 through 5 in Appendix A contain the data from the vegetation monitoring. Monitoring plot photos can also be found in Appendix A.

DESCRIPTION OF WORKSHEETS IN THIS DOCUMENT-----**Metadata**

This worksheet, which is a summary of the project and the project data.

Plots

List of plots surveyed.

Vigor

Frequency distribution of vigor classes.

Vigor by Spp

Frequency distribution of vigor classes listed by species.

Damage

List of most frequent damage classes with number of occurrences and percent of total stems impacted by each.

Damage by Spp

Damage values tallied by type for each species.

Damage by Plot

Damage values tallied by type for each plot.

Stem Count by Plot and Spp

Count of living stems of each species for each plot; dead and missing stems are excluded.
