Signature of Wilmington District Official Approving Credit Release

- 2 For NCDMS projects, the second credit release milestone occurs automatically when the as-built report (baseline monitoring report) has been made available to the NCIRT by posting it to the NCDMS Portal, provided the following criteria have been met:
  - 1) Approval of the final Mitigation Plan

1 - For NCDMS, no credits are released during the first milestone

Contingencies (if any): None

- 2) Recordation of the preservation mechanism, as well as a title opinion acceptable to the USACE covering the property
- 3) Completion of all physical and biological improvements to the mitigation site pursuant to the mitigation plan
- 4) Reciept of necessary DA permit authorization or written DA approval for porjects where DA permit issuance is not required

3 - A 15% reserve of credits is to be held back until the bankfull event performance standard has been met

Town Creek Restoration Project – Option B

Yadkin River Basin – CU# 03040105 – Stanly County, NC NCDMS Project ID No. 95026; NCDEQ Contract No. 003990

Dear Mr. Tsomides:

Please find enclosed the Final Year 3 Monitoring Report and our responses to the Division of Mitigation Services (DMS) review comments received on December 14, 2018 regarding the Town Creek Restoration Project – Option B, located in Stanly County, NC. We have revised Final Year 3 Monitoring Document in response to the referenced review comments. Each response has been grouped with its corresponding comment and is outlined below.

**Table 2** – This table should indicate the month-year of both stream monitoring (Oct 2018), and vegetation data collection (Sep 2018).

**Response** – Table 2 has been revised to include the month-year of both stream monitoring and vegetation data collection as requested.

**Cross Section Graphs** – should indicate whether it is a pool or a riffle. Understood that the x-section table has this information, but it also needs to be on the graphs so the reader can have some context without having to flip back and forth.

**Response** – The indication of whether the cross-section is a riffle or pool has been added to both the cross-section heading and the graph for each cross-section.

If you have any questions or concerns, please feel free to contact me at (704) 579-4828 or via my email address at <a href="mailto:ksuggs@mbakerintl.com">ksuggs@mbakerintl.com</a>.

Sincerely,

Kristi Suggs Project Manager

## 1.0 EXECUTIVE SUMMARY

Michael Baker Engineering, Inc. (Baker) restored 2,760 linear feet (LF) and enhanced approximately 943 LF of jurisdictional stream along UT to Town Creek. This report documents and presents the Year 3 monitoring data as required during the five-year monitoring period.

The primary restoration goals of the project are described below:

- Create geomorphically stable conditions along the channels,
- Enhance hydrologic connections between streams and the degraded riparian buffer and overall ecosystem functionality;
- Restore and protect riparian buffer functions and corridor habitat in perpetuity by establishing a permanent conservation easement.
- Improve terrestrial habitat and reduce sediment and nutrient loading to the project reaches and the Little Long Creek Watershed.

To accomplish these goals, the following objectives were identified:

- Restore existing incised, eroding, and channelized streams by creating a stable stream channel with access to its floodplain,
- Improve in-stream habitat by providing a more diverse bedform with riffles and pools, creating deeper pools and areas of water re-aeration, and reducing bank erosion,
- Prevent cattle from accessing the project boundary by installing permanent fencing and thus reduce excessive bank erosion and undesired nutrient inputs,
- Plant native species riparian buffer vegetation along stream bank and floodplain areas, protected by a
  permanent conservation easement, to increase stormwater runoff filtering capacity, improve bank
  stability, and shade the stream to decrease water temperature,
- Control invasive species vegetation within the project area and, if necessary, continue treatments during the monitoring period.

The Town Creek Restoration Project – Option B (Site) is located in Stanly County, approximately 1.5 miles west of the Town of New London, within cataloging unit 03040105 of the Yadkin Pee-Dee River Basin. The Site is located in a North Carolina Division of Mitigation Services (NCDMS) - Targeted Local Watershed (HUC 03040105060-040). Directions to the Project Site can be found in Figure 1 of Appendix A.

During Year 3 monitoring, the planted acreage performance categories were functioning at 100 percent with no bare areas or low stem density areas to report. No invasive species areas of concern, exceeding the mapping threshold were documented; however, a few species of Mimosa tree (*Albizia julibrissin*) were noted near the fence line just inside the conservation easement along the northern easement boundary that coincides with the property boundary. Presence of this invasive species likely due to encroachment from the abutting property. Another area of note was the presence of Japanese stiltgrass (*Microstegium vimineum*) along the eastern side of Vegetation Plot 6. Both areas of invasive encroachment will be treated with the proper herbicidal application method over the 2018 – 2019 winter/spring months and will be monitored and/or treated during subsequent monitoring years as needed.

Based on data collected from the eight monitoring plots during Year 3 monitoring, the average density of total planted stems per plot ranges from 486 to 769 stems per acre with a tract mean of 612 stems per acre. Therefore, the Year 3 data demonstrate that the Site has exceeded the minimum interim success criteria of 320 trees per acre by the end of Year 3 and is on track for meeting the minimum success criteria of 260 trees per acre by the end of Year 5. The presence of volunteer woody vegetation was noted in VP1, VP6, and VP 7; however, these

species were not included in the average vegetation plot data densities. Vegetation stem counts are summarized in Tables 7 and 9 of Appendix C.

The thirteen (13) permanent cross-sections located throughout the Site show minimal adjustment to stream dimension since construction. In addition, Tables 5a through 5f (Appendix B) indicate the Site has remained geomorphically stable with lateral/vertical stability and in-stream structure performance of 100% on all stream reaches and no noted areas of bank scour and/or erosion around structures. Visual observations and a review of pebble count data collected indicated that stream is sufficiently moving fines through the system. Riffles are comprised of a mix of substrates with the bed material continuing to move towards a mix of coarser substrates. Cross-sectional and pebble count data are provided in Figures 3 and 4, respectively, in Appendix D.

In-stream pressure transducers, TC FL1 and TC FL2, were installed on Reach 1 to document intermittent flow conditions throughout the monitoring year. Since post-construction installation, each gauge has documented at least one period of consecutive stream flow for the required minimum of 30 days for all three monitoring years so far, with a maximum of 109 consecutive days for TC FL1 and 156 consecutive days for TC FL2 this year. Figures 5a and 5b in Appendix E, depict the documented flow conditions for each gauge from installation through Monitoring Year 3 relative to local rainfall data, while Table 13 documents both the total cumulative days of flow and the maximum number of consecutives days of flow.

Lastly, at least five post-construction bankfull events occurred during MY3, with two of the recorded events at one foot above bankfull. Two bankfull flow events have been documented in separate years, thus the site has met the bankfull flow requirements. Documentation of the event is in Table 12 of Appendix E.

Summary information/data related to the Site and statistics related to performance of various project and monitoring elements can be found in the tables and figures in the report Appendices. Narrative background and supporting information formerly found in these reports can be found in the Baseline Monitoring Report and in the Mitigation Plan available on the NCDMS' website. All raw data supporting the tables and figures in the appendices is available from NCDMS upon request.

### 2.0 METHODOLOGY

The five-year monitoring plan for the Site includes criteria to evaluate the success of the stream and vegetation components of the project. Monitoring methods used will follow the NCDMS Monitoring Report Template, Version 1.30 - 1/15/10 and are based on the design approaches and overall project goals. To evaluate success criteria associated with a geomorphically stable channel, hydrologic connectivity, and aquatic habitat diversity, geomorphic monitoring methods will be conducted for project reaches that involve Restoration and Enhancement Level I mitigation. The specific locations of monitoring features, such as vegetation plots, permanent cross-sections, reference photograph stations and crest gauges, are shown on the CCPV sheets found in Figure 2 of Appendix B.

Stream survey data were collected to meet the requirements for a topographic ground survey to the accuracy of Class C Vertical and Class A Horizontal (21 NCAC-56 section .1606) and was geo-referenced to the NAD83 State Plane Coordinate System, FIPS3200 in US Survey Feet, which was derived from the Town Creek Restoration Project Option B's As-built Survey.

## 2.1 Stream Monitoring

Geomorphic monitoring of the Restoration and Enhancement Level I reaches will be conducted once a year for a minimum of five years following the completion of construction. These activities will evaluate the success criteria associated with a geomorphically stable channel, hydrologic connectivity, and aquatic habitat diversity. The stream parameters to be monitored include stream dimension (cross-sections), pattern (planimetric survey), profile (longitudinal profile survey), visual observation with photographic documentation, and documentation of bank full events. Additionally, monitoring methods for all reaches will include those described under Photo

Documentation of Site, Visual Assessment, and Vegetation Monitoring. The methods used and related success criteria are described below for each parameter. Figure 2 shows approximate locations of the proposed monitoring devices throughout the project site.

### 2.1.1 Morphologic Parameters and Channel Stability

#### **2.1.1.1 Dimension**

A total of thirteen (13) permanent cross-sections, nine (9) riffles and four (4) pools, were installed throughout the entire project area. Cross-sections selected for monitoring included representative riffle and pool facets for each of the three project reaches, Reach 2, 3, and 5, which implemented at least 500 linear feet of Restoration or Enhancement I activities.

Each cross-section was marked on both banks with permanent pins to establish the exact transect used. A common benchmark was also chosen to consistently reference and facilitate the comparison of year-to-year data. The cross-sectional surveys are conducted annually and include measurements of Bank Height Ratio (BHR) and Entrenchment Ratio (ER). The monitoring survey includes points measured at all breaks in slope, including top of stream banks, bankfull, inner berm, edge of water, and thalweg, if the features are present. Riffle cross-sections are classified using the Rosgen Stream Classification System (Rosgen 1994), and all monitored cross-sections should fall within the quantitative parameters defined for channels of the design stream type.

There should be little change in annual cross-sectional surveys from those collected during the post-construction as-built survey. If changes do take place, they will be evaluated to determine if they represent a movement toward a more unstable condition (e.g., down-cutting or erosion) or a movement toward increased stability (e.g., settling, vegetative changes, deposition along the banks, or decrease in width/depth ratio). Cross-sectional data is presented in Figure 3 of Appendix D.

### 2.1.1.2 Longitudinal Profile

A longitudinal profile was surveyed for the entire length of channel immediately after construction to document as-built baseline conditions for the first year of monitoring only. The survey was tied to a permanent benchmark and measurements included thalweg, water surface, bankfull, and top of low bank. Each of these measurements was taken at the head of each feature (e.g., riffle, pool) and at the maximum pool depth. Yearly longitudinal profiles will not be conducted during subsequent monitoring years unless channel instability has been documented or remedial actions/repairs are required by the USACE or NCDMS.

#### 2.1.1.3 Substrate and Sediment Transport

After construction, there should be minimal change in the pebble count data over time given the current watershed conditions and sediment supply regime. A substrate sample was collected for each riffle cross-sections where constructed riffles were installed (X1, X4, X5, X7, X9, X10, and X12). Samples collected combined with evidence provided by changes in cross-sectional data and visual assessments will reveal changes in sediment gradation that occur over time as the stream adjusts to upstream sediment loads. Significant changes in sediment gradation were evaluated with respect to stream stability and watershed changes. Bed material distribution data are located in Figure 4 of Appendix D.

### 2.1.2 Stream Hydrology

#### 2.1.2.1 Bankfull Events

The occurrence of bankfull events within the monitoring period were documented by the use of a crest gauge and photographs. The crest gauge will record the highest watermark between site visits, and the gauge will be checked at each site visit to determine if a bankfull event has occurred. The crest gauge was installed the floodplain of Reach 5 within ten feet (horizontal) of the restored channel. Photographs

will be used to document the occurrence of debris lines and sediment deposition on the floodplain during monitoring site visits.

Two bankfull flow events have been documented in separate years, monitoring year 1 had one bankfull event and monitoring year 3 had 5 bankfull events. Thus the site has met the bankfull flow requirement.

#### 2.1.2.2 Flow Documentation

A combination of photographic and flow gauge data were collected from two in-stream pressure transducers (TC FL1 and TC FL2) and a remote in-field camera that were installed on Reach 1. Collected data will document that the restored intermittent stream system continues to exhibit base flow for of at least 30 consecutive days throughout each monitoring year under normal climatic conditions. In order to determine if rainfall amounts were normal for the given year, rainfall gauge data was obtained from the nearest Stanly County weather station (CRONOS Database, NEWL – North Stanly Middle School, if available) and compared to the average monthly rainfall amounts from the Stanly County WETS Table (USDA 2018). If a normal year of precipitation does not occur during the first five years of monitoring, flow conditions will continue to be monitored on the site until it documents that the intermittent streams have been flowing during the appropriate times of the year.

Flow data and photographic documentation collected during Year 3 monitoring are located in Appendix E.

## 2.1.3 Photographic Documentation of Site

Photographs were used to document restoration success visually. Reference stations and cross-section photos were photographed during the as-built survey; this will be repeated for at least five years following construction. Reference photos were taken once a year, from a height of approximately five to six feet. Permanent markers ensure that the same locations (and view directions) are utilized during each monitoring period. Photographers will make an effort to consistently maintain the same area in each photo over time. Selected site photographs are shown in Appendix B for reference stations and Appendix D for cross-sections.

#### 2.1.3.1 Lateral Reference Photos

Reference photo transects were taken of the right and left banks at each permanent cross-section. A survey tape was captured in most photographs which represents the cross-section line located perpendicular to the channel flow. The water line was located in in the center of the photograph as much as possible to capture bank, riparian and channel conditions.

#### 2.1.3.2 Longitudinal Station Photos

Stream reaches were photographed longitudinally beginning at the upstream portion of the Site and moving downstream. Photographs were taken looking both upstream and downstream at delineated locations throughout the restored stream valley. The photograph points were established close enough together to provide an overall view of the reach lengths, primary grade control structures, and valley crenulations. The angle of the photo depends on what angle provides the best view was noted and will be continued in future photos. Site photographs are located in Appendix B.

#### 2.1.4 Visual Assessment

Visual monitoring assessments of all stream sections will be conducted by qualified personnel twice per monitoring year with at least five months in between each site visit. Photographs will be used to document system performance and any areas of concern related to stream bank stability, condition of in-stream structures, channel migration, aggradation/degradation, headcuts, live stake mortality, impacts from invasive plant species or animal species, floodplain vegetative conditions, and condition of pools and riffles. The photo locations will be shown on a plan view map and descriptions will be

documented as either stream problem areas (SPAs) or vegetative problem areas (VPAs) in there associated monitoring assessment tables located in Appendix B.

## 2.2 Vegetation Monitoring

To determine if the criteria are achieved, vegetation-monitoring quadrants were installed and are monitored across the restoration site in accordance with the CVS-NCEEP Protocol for Recording Vegetation, Version 4.0 (Lee 2006). The vegetation monitoring plots are a minimum of 2 percent of the planted portion of the site with eight plots established randomly within the planted riparian buffer areas. No monitoring quadrants were established within the undisturbed wooded areas of the project area. The size of individual quadrants are 100 square meters for woody tree species.

Level 1 CVS vegetation monitoring was conducted between spring, after leaf-out has occurred, and fall prior to leaf fall. Individual quadrant data provided during subsequent monitoring events will include species composition, density, survival, and stem height. Relative values were calculated, and importance values were determined. Individual seedlings were marked to ensure that they can be found in succeeding monitoring years. Mortality was determined from the difference between the previous year's living, planted seedlings and the current year's living, planted seedlings.

The interim measure of vegetative success for the site is the survival of at least 320, 3-year old, planted trees per acre at the end of Year 3 of the monitoring period. The final vegetative success criteria are the survival of 260, 5-year old, planted trees per acre at the end of Year 5 of the monitoring period.

Photographs were used to visually document vegetation success in sample plots and are located in Appendix C.

#### DESCRIPTION OF WORKSHEETS IN THIS DOCUMENT-----

MetadataDescription of database file, the report worksheets, and a summary of project(s) and project data.Proj, plantedEach project is listed with its PLANTED stems per acre, for each year. This excludes live stakes.

**Proj, total stems** Each project is listed with its TOTAL stems per acre, for each year. This includes live stakes, all planted stems, and all natural/volunteer stems.

**Plots**List of plots surveyed with location and summary data (live stems, dead stems, missing, etc.).

VigorFrequency distribution of vigor classes for stems for all plots.Vigor by SppFrequency distribution of vigor classes listed by species.

**Damage**List of most frequent damage classes with number of occurrences and percent of total stems impacted by each.

Damage by SppDamage values tallied by type for each species.Damage by PlotDamage values tallied by type for each plot.

**Planted Stems by Plot and Spp** A matrix of the count of PLANTED living stems of each species for each plot; dead and missing stems are excluded.

ALL Stems by Plot and spp A matrix of the count of total living stems of each species (planted and natural volunteers combined) for each plot; dead and missing stems are excluded.

PROJECT SUMMARY-----

## **APPENDIX E**

Hydrologic Data

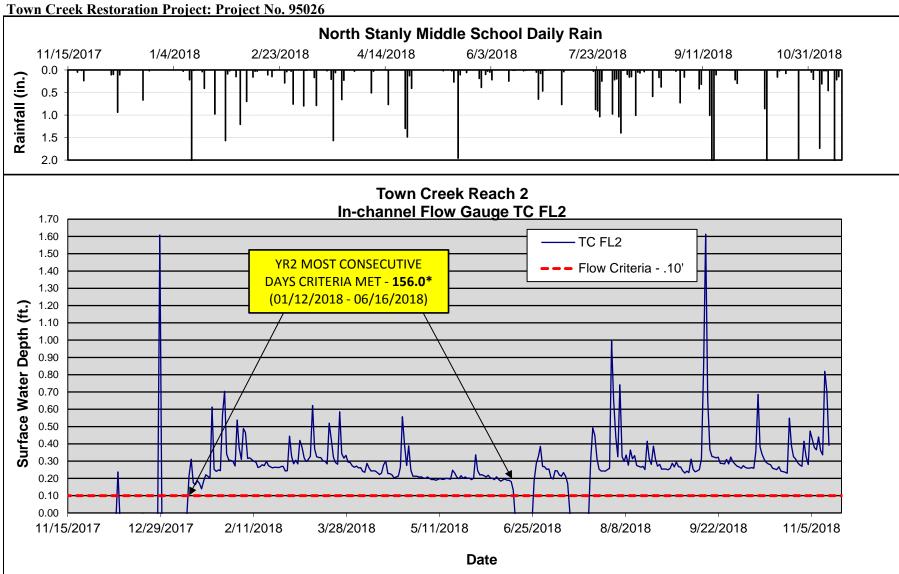

Figure 5a. In-Stream Flow Gauge Graphs

Town Creek Restoration Project: Project No. 95026

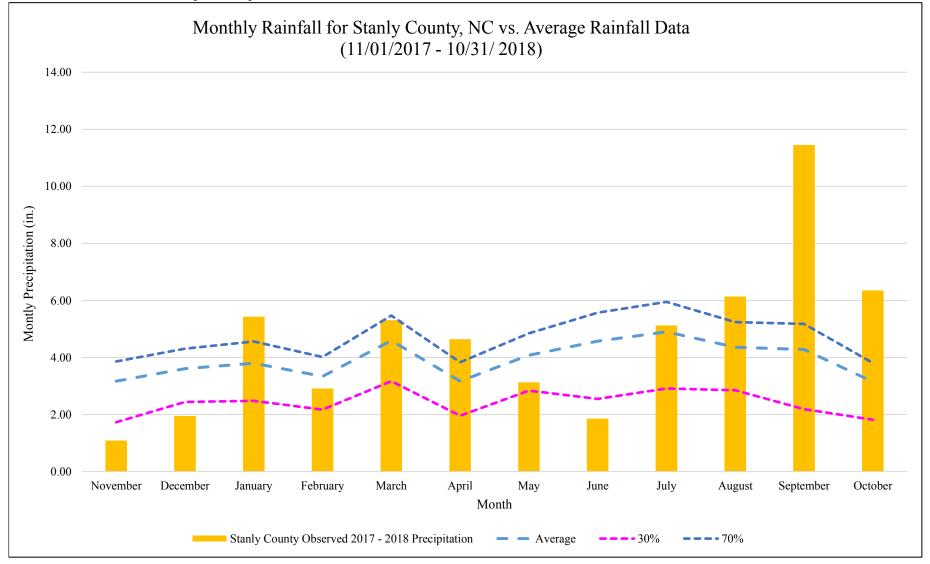

<sup>\*</sup> Surface water flow is estimated to have occurred when the pressure transducer reading is equal to or above 0.1 feet in depth.

Figure 5b. In-Stream Flow Gauge Graphs

<sup>\*</sup> Surface water flow is estimated to have occurred when the pressure transducer reading is equal to or above 0.1 feet in depth.

Figure 6. Monthly Rainfall Data
Town Creek Restoration Project: Project No. 95026

Historic rainfall data from WETS Station: ALBEMARLE, NC0090

Observed 2017 - 2018 Precipitaion from CHRONOS Station NEWL, North Stanly Middle School

MICHAEL BAKER ENGINEERING, INC., DMS PROJECT NO. 95026 TOWN CREEK RESTORATION PROJECT - OPTION B YEAR 3 MONITORING REPORT - 2018, YEAR 3 OF 5

	n of In-stream Flow Cond tion Project: DMS Projec		
Flow Gauge ID	Reach Location	Consecutive Days of Flow <sup>1</sup>	Cumulative Days of Flow <sup>2</sup>
TCFL1	Reach 1 Station 11+05	109	248
TCFL2	Reach 2 Station 13+02	156	287

## Notes:

Flow success criteria for the Site is stated as: A surface water flow event will be considered intermittent when the flow duration occurs for a minimum of 30 days.

<sup>&</sup>lt;sup>1</sup>Indicates the number of consecutive days within the monitoring year where flow was measured.

<sup>&</sup>lt;sup>2</sup>Indicates the number of cumulative days within the monitoring year where flow was measured.
