

1999 Auburn NC Tower Multi-Elevation Ozone and Volatile Organic Compound Monitoring Project Report

Ambient Monitoring Section

Division of Air Quality

Department of Environment and Natural Resources

Report No. 2000.02

November 2000

Abstract

The 1999 Multi-Elevation Ozone and Volatile Organic Compound Monitoring Project at the Auburn-TV Tower was conducted at 8 feet (ground), 250 feet, 420 feet, 820 feet and 1420 feet elevations. Ozone was monitored continuously at the 8 feet, 250 feet, 420 feet, and 1420 feet levels from April through October. Morning and afternoon integrated 3-hour volatile organic compound samples were collected in polished stainless steel canisters at the 8 feet, 820 feet, and 1420 feet levels for analysis of PAMS hydrocarbons.

Keywords

Ozone, Multi-elevation Ozone Monitoring, Diurnal Ozone Patterns, PAMS, Hydrocarbons

Authors

Charles O. Davis III and Thomas L. Manuszak

Previous Reports: 1993-1998 and Related Studies

The 1993 - 1998 reports published by the Division of Air Quality outlined the data collected, monitoring methods and boxplots of daily ozone concentrations at three levels. The previous reports are available upon request.

If you have any questions concerning this report please contact
Charles Davis at 919-715-0664.

Acknowledgments

We thank Wade Daniel, Frank Stellitano, Kip Davenport, and Hoke Kimball for their technical contribution and assistance. We also thank George C. Murray Jr. for his managerial guidance; the Electronics and Calibration Branch (ECB) staff for performing the operational audits and maintaining the monitoring equipment; Wayne Cornelius, Ph.D. Tahmina Islam, and Victoria Georgiou for data processing assistance; and Phyllis Lowry for hydrocarbon sample analysis.

1. Introduction

The Ambient Monitoring Section is responsible for evaluating the ambient air quality of the State of North Carolina for the Division of Air Quality (DAQ) of the Department of Environment and Natural Resources. The Ambient Monitoring Section supports this evaluation through its operation of criteria pollutant (O_3 , CO, SO_2 , PM_{2.5}, NO_2 , Pb) monitoring stations and special purpose (HAPS metals, NOy, hydrocarbons) monitoring stations throughout the state. Ground level ozone and its associated health effects continue to be a primary concern of DAQ. In 1999, there were forty-five (45) ground level ozone monitoring sites in operation in North Carolina. Thirty-three (33) of these ozone monitoring sites were operated by the Ambient Monitoring Section with the remaining sites operated by four other agencies. These agencies are the Eastern Band of the Cherokee Indians (1 site), Forsyth County Environmental Affairs Department (4 sites), and Mecklenburg County Department of Environmental Protection (3 sites), and Western NC Regional Air Pollution Control Agency (4 sites). The Auburn-TV Tower (designated "Tower" in this report) is a Special Purpose Monitoring site (SPM) and is the only multi-elevation monitoring site in North Carolina. This report describes the ozone monitoring equipment, the operation and calibration procedures employed, the hydrocarbon sampling equipment, the hydrocarbon analytical procedures, and the data collected during the 1999 ozone season. In 1999, meteorological measurements of wind speed, wind direction, and temperature were planned, but due to operational difficulties (radio frequency interference) these parameters were not determined. Efforts are continuing to collect multi-level meteorological data at the tower.

Ozone and Volatile Organic Compound Monitoring Study

The Ozone Season in North Carolina is from April 1 to October 31. In 1997, the National Ambient Air Quality Standard (NAAQS) for ozone was established at >0.08 parts per million (ppm) 8-hr average. In 1999, there were 541 verified exceedances of this new ozone standard in North Carolina. The ozone level at one or more of the six monitoring sites in the immediate Raleigh area exceeded the new 8-hour ozone standard 29 days between May 28 and August 28 for a total of 84 exceedances. On two days during the season, all monitors in the immediate Raleigh area reported 8-hour averages exceeding the ozone standard. The ground level tower monitor reported ozone concentrations exceeding this new standard on 22 days. The upper level monitors at the tower (which do not conform to the siting criteria established for NAAQS) reported 78 8-hour average ozone levels greater than the standard over 30 different days between May 28 and August 28.

Morning and afternoon 3-hour integrated PAMS hydrocarbon samples were collected in Summa™ Canisters approximately once a week starting May 31 through September 8 at three levels for a total of 14 hydrocarbon sample sets. These samples were collected and analyzed in accordance with the Photochemical Assessment Monitoring Station procedures for 56, C₂ - C₁₂, hydrocarbon compounds. One of these compounds is biogenic, namely isoprene, and the other 55 compounds are directly related to man's activities.

2. Study Site

The Tower site is a Special Purpose Monitoring (SPM) site established in May 1993 by the DAQ. The site is located approximately 20 kilometers southeast of Raleigh, NC, at 35.68.33 Latitude and -78.55.00 Longitude, approximately 300 meters southwest of US-70 a Type 2 Road (Expressway), and is 97.5 meters Elevation Above Sea level (Figure 1). It has a "suburban" Location Setting with "agricultural" Land Use. US-70 usage is 42,000 vehicles per day. The television and radio broadcasting tower at this site is 2,000 feet tall and was put into service in October 1990 as a replacement for the previous tower that collapsed in December 1989. In 1993 - 1995, the ozone determinations were performed at ground level, 820 feet level and 1420 feet level. In 1996, the ozone monitoring levels were changed to ground level, 250, 420, and 1420 feet elevations and were continued to be used in 1997, 1998, and 1999. These levels were selected because of the presence of platforms. The platforms provide work space for the convenient installation of particulate (ozone pretreated) filters on the intake side of the Teflon FEP® ozone sampling lines. The filters prevent particulate matter from depositing on the inside of the sampling tubing. The upper levels of the tower are accessed by a two-person elevator in the center of the Tower.

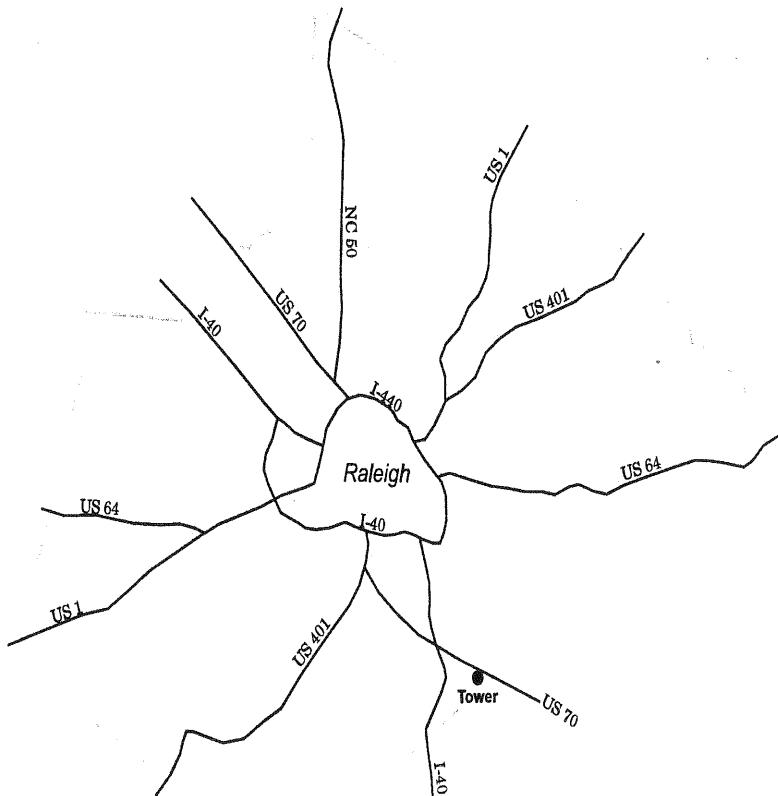

Figure 1. Auburn Tower Location in Wake County, North Carolina

3. Ozone Monitoring

The ozone sample assembly at each elevated level includes a 90 mm Teflon® filter holder with a 5 μm Teflon® particulate filter. The probes are located on the southwest part of the tower for unobstructive exposure to the predominant southwesterly summer winds. Each probe arm, made of stainless steel tubing, extends approximately 2 meters away from the tower platform with a 60 degree downward bend on the arm to minimize precipitation entering the probe line. To further minimize the moisture/precipitation problem, the FEP lines stop two feet inside the end of the stainless steel probe arm. The ends of the probe are covered with stainless steel screens. Before sampling begins on the tower, the long sample lines are inspected for water and obvious breaks and repairs are performed. Each line was then disconnected at the 90 mm filter, capped off and pressure tested to check for leaks in the long sample lines. No leaks were detected and the lines were reattached to the filters and readied for sampling. The 90 mm particulate filter at each sampling platform was replaced with a new ozone conditioned filter and filter assembly which was replaced monthly thereafter. Figure 2 presents the configuration of the monitoring system at this special

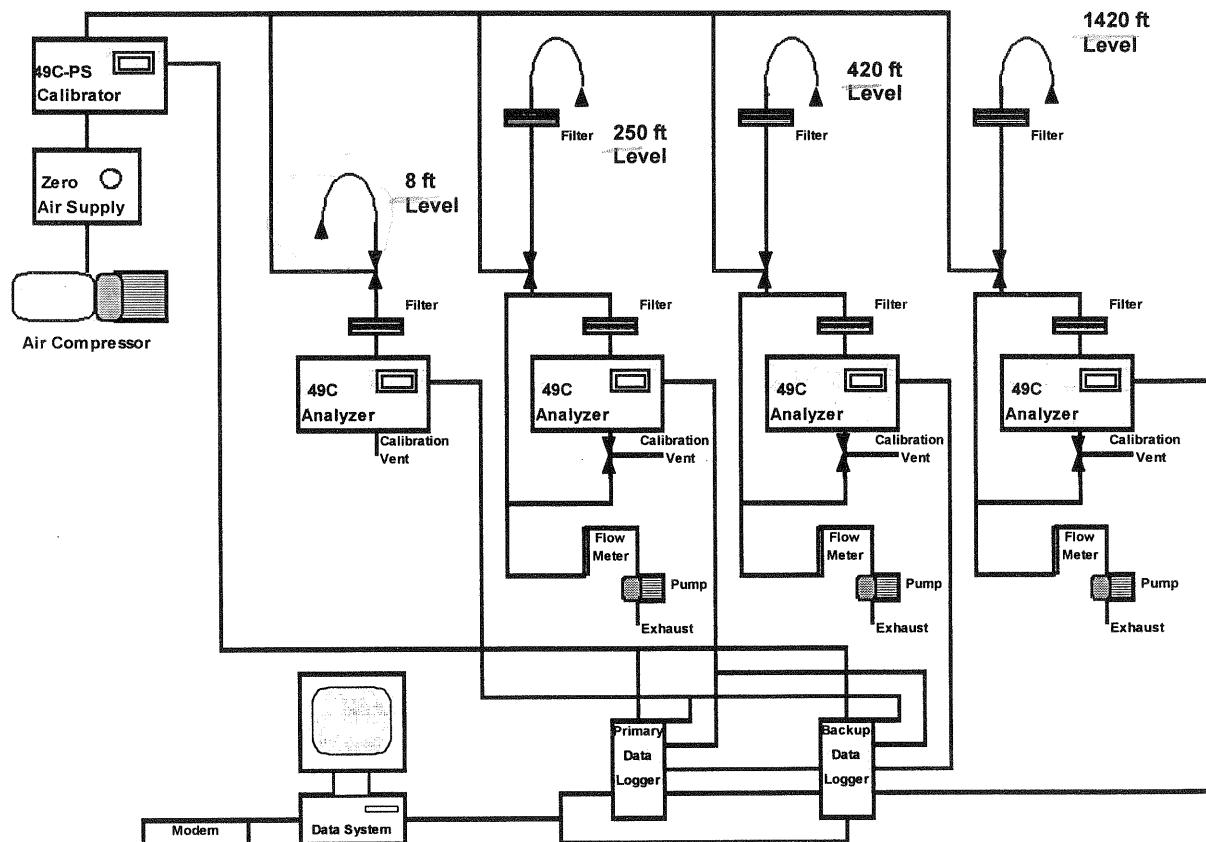

Figure 2. Ozone Monitoring, Calibration, and Data Collection System Configuration

site. All of the ozone monitoring systems are housed in a 12' x 8' temperature controlled building located adjacent to the base of the tower. The upper level ozone sampling lines are attached to the superstructure of the tower connecting each level directly to a dedicated 10 liter per minute sampling pump to reduce the sample residence time in the sampling lines. Each level has a dedicated ozone analyzer. The ozone analyzer, calibrator, zero air supply, air compressor, and the data collection system are also located in this building. Each of the upper levels Teflon sampling lines was leak tested prior to the ozone monitoring season.

3.1 Ozone Monitoring Methods

Ozone was measured using the ultraviolet photometric principle. In 1998, the monitors and calibrators for the entire state-operated ozone monitoring network in North Carolina were replaced with Thermo Environmental Inc. Model 49C Ozone Analyzers and Model 49C-PS Ozone Calibrators. The TEI Model 49C is designated by the USEPA as an Equivalent Method for the measurement of ambient concentrations of ozone pursuant with the requirements defined in the Code of Federal Regulations, Designated Equivalent Method Number, EQOA-0880-047. A single TEI Model 49C-PS calibrator traceable to the NC Primary Ozone Standard Photometer was used to perform all calibrations and precision checks for the four ozone monitors. This same calibrator was used to perform nightly autocalibrations of each of the analyzers. The outputs of the monitors were connected to a data logger and to a "back-up" data system. The Figure 3 is a schematic of the sampling and calibration pathways for each ozone analyzer.

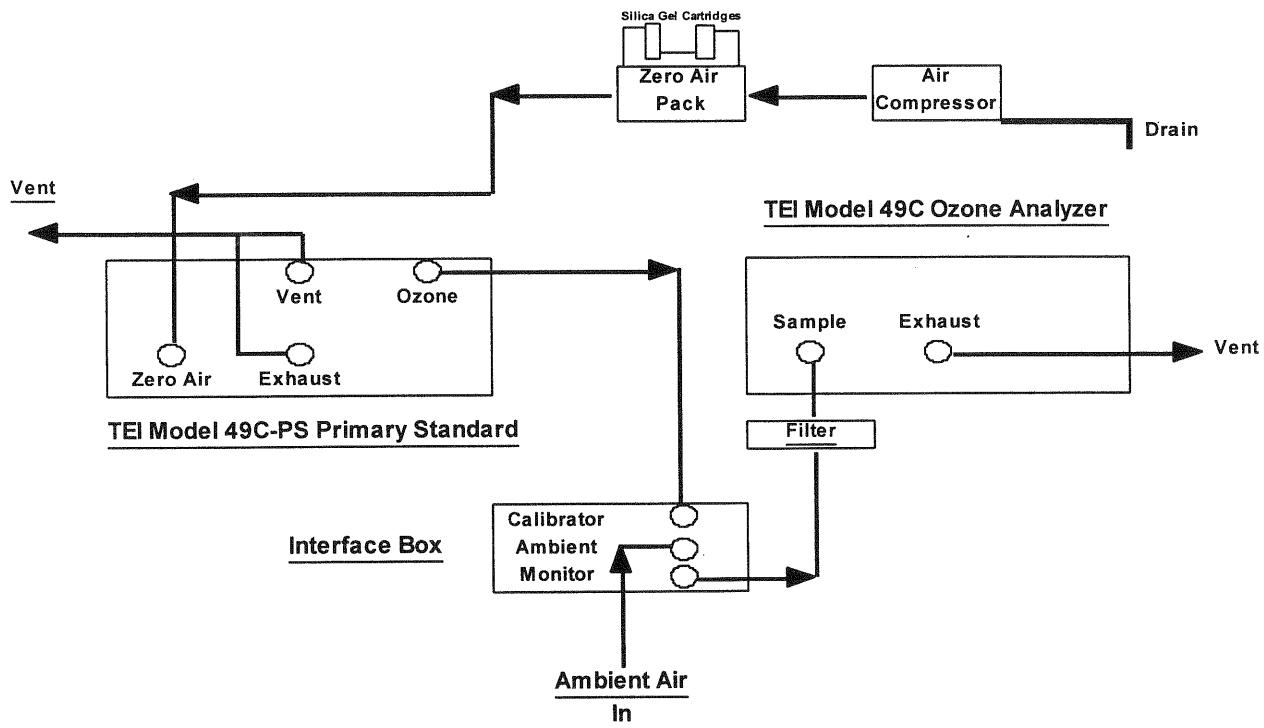

Figure 3. Ozone Calibration and Monitoring Schematic.

3.2 Ozone Monitor Adjusted Calibration and Nightly Autocalibrations

The TEI Model 49C Ozone Analyzers are operated on the 0.000 to 0.250 parts per million range. Prior to the beginning of the ozone monitoring season, an Adjusted Calibration is performed on each of the four ozone analyzers per Section 2.7 "Ozone Monitoring Using the Thermo Environmental Continuous Monitor and Data Logger" of the North Carolina Standard Operating Procedures and Quality Assurance Plan Section 2.7 as approved by the EPA. This calibration adjusts the ozone analyzer to read exactly the same as the on-site Ozone Primary Standard Calibrator, which is traceable to the North Carolina Primary Ozone Standard Photometer, which has been verified by the EPA Region 4 Reference Photometer. The ozone analyzer is calibrated at 0.000, 0.050, 0.090, 0.160, and 0.225 ppm ozone. The acceptance criteria for an adjusted calibration are as follows:

<u>Primary Standard</u>	<u>Ozone Analyzer</u>
0.000 ppm	0.000 ppm \pm 0.003 ppm
0.050 ppm	0.050 ppm \pm 0.003 ppm
0.090 ppm	0.090 ppm \pm 0.003 ppm
0.160 ppm	0.160 ppm \pm 0.003 ppm
0.225 ppm	0.225 ppm \pm 0.003 ppm

Each night throughout the monitoring season, an unadjusted autocalibration is performed on each of the analyzers at 0.000, 0.050, 0.090, and 0.225 ppm ozone generated by the on-site Primary standard calibrator and recorded by the data collection system. Each autocalibration requires approximately 45 minutes to complete per analyzer. The nightly autocalibrations of the four ozone analyzers at this site occur between 3 am. and 7 am.

3.3 Unadjusted Calibrations and Site Operator Inspections

In accordance with Section 2.7 of QA/SOP the site operator performs a thorough site inspection, equipment evaluation, a full manual Unadjusted Calibration and Precision Check of each ozone analyzer, and backs up the data system on at least a biweekly basis. These site visits are to verify and document instrument operating parameters and performance and archive collected data. These site inspections and unadjusted calibrations are performed before 11 am due to the diurnal pattern of the formation of ground level ozone. During these visits the operator replaces and conditions the $5\mu\text{m}$ particulate filter (located at the back of each instrument), replaces silica gel cartridges on the zero air pack, and performs a "data backup" of all the data collected since the previous site visit. The operator records his activities in the Site Logbook and documents the site evaluation and unadjusted calibration results in the Ozone Monitoring Logbook.

The site operator determines the ozone analyzer performance while challenging the monitor with 0.000, 0.050, 0.090, 0.160, and 0.225 ppm ozone generated by the

onsite ozone primary standard. The following criteria have been established to evaluate analyzer performance:

<u>Site Primary Standard</u>	<u>Ozone Analyzer</u>
0.000 ppm	0.000 ppm \pm 0.003 ppm
0.050 ppm	0.050 ppm \pm 0.003 ppm
0.090 ppm	0.090 ppm \pm 0.003 ppm
0.160 ppm	0.160 ppm \pm 0.005 ppm
0.225 ppm	0.225 ppm \pm 0.010 ppm

If the analyzer does not meet these performance criteria, the site operator first troubleshoots the analytical system and then performs an adjusted calibration.

3.4 Ozone Data Collection Period.

Ozone monitoring at the ground level of the Tower began on April 1 and continued through October 31, 1999. Monitoring at the upper levels began on May 14. The 1999 ozone monitoring periods for all levels at the Auburn Tower Site are listed below:

<u>Level</u>	<u>Start</u>	<u>End</u>
Ground Level	April 1, 1999 at 0000 hr	Oct. 31, 1999 2300 hr
250 Feet Level	May 14, 1999 at 1000 hr	Sept. 14, 1999 1800 hr
420 Feet Level	May 14, 1998 at 1300 hr	Sept. 14, 1999 1800 hr
1420 Feet Level	May 14, 1998 at 1300 hr	Sept. 14, 1999 1800 hr

Ozone monitoring was performed at the Ground Level until the end of the ozone monitoring season (October 31, 1999). On September 14, 1999, the Tower ozone monitoring site was shut down in anticipation of Hurricane Floyd to protect the equipment. The Ground level monitor was reactivated on September 21 but the upper levels were not restarted. The data completeness for 1999 exceeds 90% at all levels.

3.5 Ozone Monitor Accuracy Audits

Accuracy audits are performed to evaluate and document the performance of the site monitoring system. The State of North Carolina DAQ Ambient Monitoring Section independently conducts accuracy audits of all ozone monitoring sites operated by the state and also participates in the National Performance Audit Program (NPAP) conducted by the USEPA. Each ozone monitoring site operated by NC participates in the NPAP audit.

The NC Accuracy Audit was performed on June 18, 1999, for the surface, 250, 420, and 1420 feet levels. The audit was performed by the Electronics and Calibration Branch (ECB) using a separate Thermo Environmental Model 49C-PS Primary Standard traceable to the NC Primary Ozone Standard Photometer. The audit device is taken to the site and is plumbed directly to the ozone analyzer to be audited. After

the analyzer and audit device have stabilized, the actual concentration generated by the audit device is compared to the analyzer's data logger response to this known concentration. The procedure is used for each audit point (0.000, 0.050 ppm, 0.090, 0.160, 0.225 ppm). The percent difference for each point is calculated as follows:

$$d_2 = \frac{(C_M - C_A) \times 100}{C_A}$$

Where:

C_M = average ozone concentration measured

C_A = average true concentration of audit gas produced by the audit calibrator.

The results of the NC Accuracy audit for each monitor are presented in Table 1.

Table 1. North Carolina Ozone Accuracy Audit

Ground Level			250 Ft Level			420 Ft Level			1420 Ft Level		
Audit Actual	Monitor Indicated	% Diff									
0.001	0.001	NA	0.001	0.001	NA	-0.001	0.000	NA	0.002	0.001	NA
0.050	0.049	2.0	0.050	0.049	-2.0	0.049	0.048	-4.0	0.050	-0.049	-2.0
0.090	0.091	1.1	0.090	0.090	0.0	0.089	0.089	-1.1	0.090	0.091	1.1
0.160	0.162	1.3	0.160	0.162	1.3	0.159	0.160	0.0	0.160	0.165	3.1
0.225	0.228	1.3	0.225	0.228	1.3	0.187	0.226	0.4	0.225	0.232	3.1
	Avg	1.4		Avg	1.2		Avg	1.4		Avg	2.3

The data from ground level ozone analyzer at this special purpose monitoring site is reported to the EPA and therefore was included in the 1999 National Performance Audit Program (NPAP) audit. The results in parts per billion ozone of that audit performed on May 20, 1999 are presented in Table 2:

Table 2. 1999 NPAP Accuracy Audit Results

NPAP Audit Results						NPAP			% Diff		
Date	Temp	BP	Zero	Low	High	Actual Value			Low	High	Mean
4/28	24	766	-1	78	173	0.3	74	167.8	5.4	3.1	4.25

4. Volatile Organic Compound Sampling and Analysis

Hydrocarbons are an important component of the ozone production cycle and a better understanding of the speciation and dispersal in the atmosphere is needed to better understand the complex ozone atmospheric chemistry. The Tower site provides an unique opportunity to collect ambient hydrocarbon samples simultaneously at ground level, 820 feet, and 1420 feet. Samples were collected at 6 - 9 am. and from 2 - 5 pm at all levels.

A schematic of the hydrocarbon sampling system is shown in Figure 4. The ground level hydrocarbon sampling system is housed within the same building adjacent to the tower as the ozone monitoring systems. The hydrocarbon collection systems on the upper levels (820 feet and 1420 feet) are housed in specially constructed weather proof enclosures. These two upper levels were chosen because of the availability of electrical power to operate the pump and the timing systems. The sampling system consist of two seven-day timers which activate a metal bellows pump, elapsed time meters, and a canister specific two-way solenoid valve. All sampling lines are constructed of 1/8" ID gas chromatography grade stainless steel tubing. The upper level sampling probes extend 2 meters to the southwest from the tower and the ground level probe is located 8 feet above the ground extending approximately 4 feet from the building located at the base of the tower.

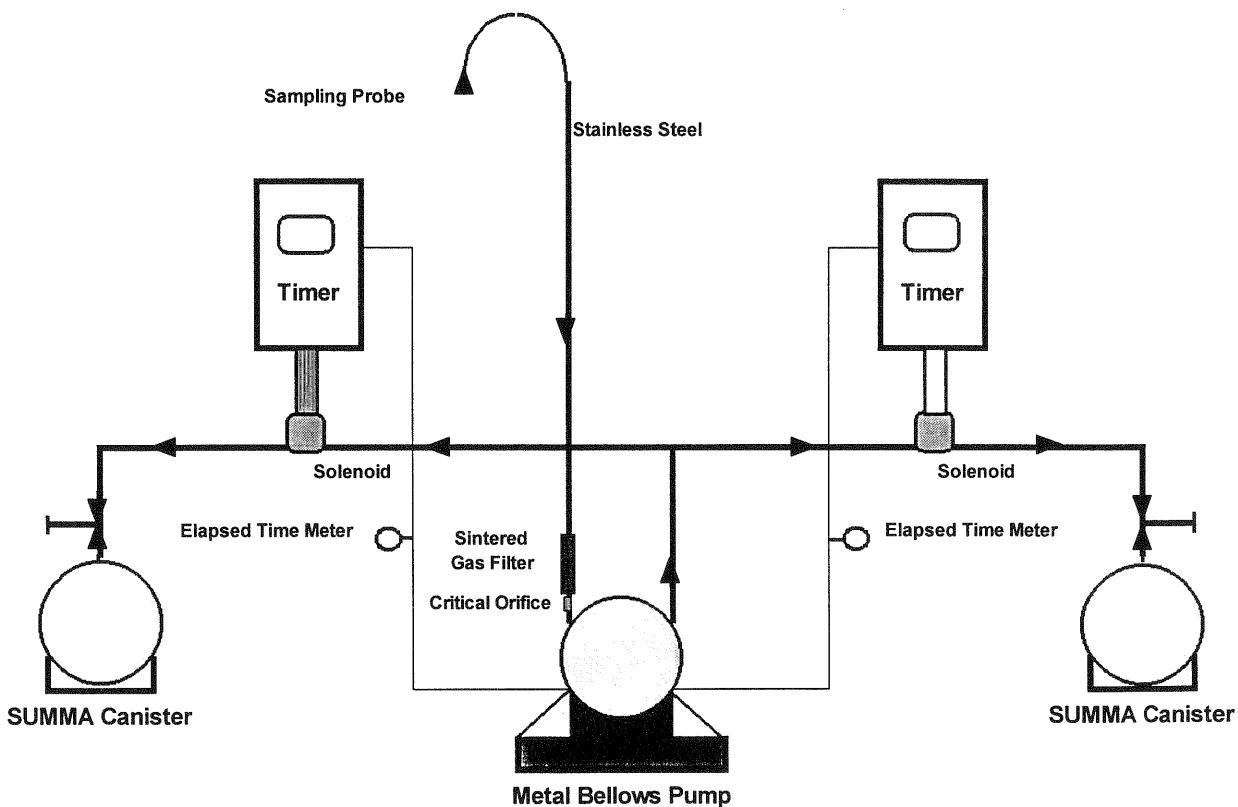

Figure 4. Hydrocarbon Sampling System

4.1 Volatile Organic Compound Analytical Procedure

The ambient air samples collected in the passivated stainless steel Summa™ canisters using the sampler described above are analyzed at the Ambient Monitoring Section Hydrocarbon Speciation Laboratory in Raleigh. In addition to the PAMS hydrocarbon sampling sites operated by NC, this laboratory also analyzes the samples collected by locally operated programs.

The instrumentation used to analyze the ambient air samples for the targeted C2 through C12 hydrocarbons (ethane through dodecane) is a two-column dual Flame Ionization Detector (FID) gas chromatograph. The target compounds are identified by comparison to retention times of the known compounds included in the calibration standard. This standard provided by the EPA is used for both peak identification and for determining the concentration of each respective compound. The two columns are a 50 m x 0.32 mm Al₂O₃/Na₂SO₄ Plot™ column and a 50 m x 0.22 mm Reste™ c methyl silicone column each of which is directed to a dedicated FID for the efficient separation and identification of each compound. The Plot™ column is used to separate the ethane (C2) through 1-Hexene (C6) and the Methyl Silicone column is used to separate Hexane (C6) through Dodecane (C12).

The 600 cc sample passes through a Nafion Drier to remove the moisture from the sample. Moisture has a detrimental effect on the Plot™ column and must be removed prior to the column. The sample then is transferred into an automatic thermal desorption system that uses an electrically cooled packed cold trap to produce a concentrated sample prior to injection. The rapid heating (40 °C/sec.) of the cold trap ensures efficient injection of the sample onto the analytical column. The gas chromatograph oven is then temperature ramped in two stages up to 200 °C. The detectors are maintained in an isothermal condition at 250 °C. As compounds elute from each specific column, the dedicated detector response is proportional to the concentration of each compound. The greater the concentration of a compound in the sample, the greater the detector response. The detector response is then compared to the detector response to a known concentration of that compound found in the calibration standard to determine the concentration in the sample. The concentration of the compound in the sample is reported as parts per billion carbon (ppbc).

A total of 57 compounds are identified by this chromatographic technique. These compounds are methane and the 56 PAMS target compounds. The results are reported for each individual PAMS target compound and grouped as Total Non-Methane Organic Compounds, NMOC, which includes any unknown compounds (which also are quantified as ppbc based upon detector response but not identified) and the total of known compounds. The list of PAMS 56 targeted organic compounds is presented in Table 3.

Table 3. Target Volatile Organic Compounds

METHANE	2-METHYLPENTANE	OCTANE
ETHANE	3-METHYLPENTANE	ETHYLBENZENE
ETHYLENE	ISOPRENE	M/P-XYLENE
PROPANE	1-HEXENE	STYRENE

CYCLOPENTANE	3-METHYLHEXANE	O-ETHYLTOLUENE
ISOPENTANE	2,2,4-TRIMETHYLPENTANE	1,2,4-TRIMETHYLBENZENE
PENTANE	HEPTANE	DECANE
TRANS-2-PENTENE	METHYLCYCLOHEXANE	1,2,3-TRIMETHYLBENZENE
1-PENTENE	2,3,4-TRIMETHYLPENTANE	M-DIETHYLBENZENE
CIS-2-PENTENE	TOLUENE	P-DIETHYLBENZENE
2,2-DIMETHYLBUTANE	2-METHYLHEPTANE	UNDECANE
2,3-DIMETHYLBUTANE	3-METHYLHEPTANE	DODECANE

4.2 Volatile Organic Compound Calibration

The PAMS 56 component calibration standard is analyzed each day prior to analysis of the samples collected in the field. This standard is obtained from Scott Specialty Gases. Via this standard, which ranges in concentration from 21 ppbc to 62 ppbc, individual compound response factors are determined. These organic species response factors are used in subsequent sample analysis to determine the concentration of each compound in the sample.

4.3 Volatile Organic Compound Sampling Period

During 1999, PAMS volatile organic compound samples were collected at eight different sites throughout NC. The Tower site is one of these sites. Due to limited access to the upper levels of the tower, samples were collected once per week from the

period of May 31 through September 8, 1999. PAMS hydrocarbon samples were collected simultaneously at all levels at the same time on the same day. Through the use of the seven-day timers the day of sampling was pre-programmed based on long range weather forecast in order to coincide with warm clear days with the greatest ozone formation potential. Three-hour integrated hydrocarbon samples were collected in the morning (6 am - 9 am) and the afternoon (2 pm - 5 pm) at all levels. The sampling days and samples collected are listed in Table 4.

Table 4. Hydrocarbon Sampling Days

Date	Ground Level		820 Feet Level		1420 Feet Level	
05/31	AM	PM	AM	-0-	AM	PM
06/14	AM	PM	AM	PM	AM	PM
06/21	AM	-0-	AM	-0-	AM	PM
06/28	AM	PM	AM	-0-	AM	PM
07/05	-0-	PM	AM	PM	AM	PM
07/10	AM	PM	AM	-0-	AM	PM
07/19	AM	PM	AM	-0-	-0-	PM
07/26	AM	PM	AM	-0-	-0-	PM
07/30	AM	PM	AM	PM	-0-	PM
08/06	AM	PM	AM	-0-	AM	PM
08/13	AM	-0-	-0-	-0-	AM	-0-
08/24	AM	-0-	-0-	PM	-0-	PM
09/01	AM	PM	AM	PM	-0-	PM
09/08	AM	PM	-0-	PM	AM	PM

note: " -0-" denotes sample not successfully collected

Considerable sample collection difficulty was experienced at the 820 and 1420 feet levels throughout the season. The lost samples have been attributed to thunderstorm activity and power demand fluctuations.

5. Ozone and VOC Monitoring Results

5.1 Ozone Monitoring Results

During 1999, ozone was monitored at the Tower site throughout the late spring, summer, and early fall. The Tower enabled the Ambient Monitoring Section to monitor ozone on a continuous basis at ground level, 250 feet, 420 feet, and 1420 feet simultaneously. The ground level ozone monitor began collecting data on April 1 and operated until October 31, 1999. The 250 feet, the 420 feet, and the 1420 feet levels operated from May 14 until they were shut down on September 14, just prior to the effects of Hurricane Floyd, to protect the equipment. For the period of operation at this site, data completeness for each level exceeded 94%. It should be noted that a valid ozone monitoring season completeness is established as being greater than 75%. Table 5 below presents the monthly hourly average (Avg) and monthly hourly maximum (Max) for each monitoring level in parts per million.

Table 5. Monthly Average and Maximum Ozone Concentration (ppm) All Levels

	Ground		250 Ft		420 Ft		1420 Ft	
	Avg	Max	Avg	Max	Avg	Max	Avg	Max
April	0.042	0.086	NA	NA	NA	NA	NA	NA
May	0.039	0.100	0.052	0.107	0.056	0.106	0.062	0.108
June	0.039	0.123	0.046	0.128	0.047	0.126	0.057	0.121
July	0.042	0.126	0.052	0.124	0.054	0.123	0.064	0.126
Aug	0.046	0.127	0.056	0.122	0.059	0.131	0.061	0.124
Sept	0.030	0.089	0.040	0.090	0.041	0.088	0.046	0.087
Oct	0.019	0.063	NA	NA	NA	NA	NA	NA

The monthly average ozone concentrations show a pattern of increasing concentration with height for each month for which data are available. The maximum concentrations do not exhibit the same pattern of increasing with height. This is expected, for the ozone maximums occur during the afternoon when the air column is well mixed. The historical 1-hour ozone standard (>0.125 ppm) was exceeded at the Tower twice at the ground level and 4 times at the upper levels during 1999. The old 1-hour standard was exceeded 20 times across the state in 1999 including eight times in the immediate Raleigh area including the Tower.

In 1997, the EPA revised the National Ambient Air Quality Standard for ozone to >0.08 ppm measured over eight hours. The standard is attained when the expected number of days per year on which the average fourth highest concentration exceeds this by at least 0.005 ppm is equal to or less than one. An average of the fourth highest ozone concentrations for each year over a three year period is used to determine whether an area is in or out of compliance. Effectively the new ozone standard for an overlapping 8-hour average has been established at 0.085 ppm. In 1999 there were 541 exceedances of the new 8-hour ozone standard at the 45 statewide reporting monitoring sites on 68 days. Of these exceedances, 22 were from the ground level ozone monitor located at the Tower. The other upper levels (250 ft., 420 ft., and 1420

ft.) monitoring ozone at this site do not meet the siting criteria as specified by the EPA, and thus were not reported to the EPA nor included in the statewide totals. Table 6 provides a list of all the 8-hour exceedances at the ground level monitor and the 8-hour averages at the upper levels that were also greater than or to 0.084 ppm ozone.

Table 6. 1999 Ozone Exceedances and Upper Level 8-Hour Averages >0.084 ppm.

Total # >0.084	22		27		24		30

It should be noted that:

1. For 21 days, the 8-hour average was greater than 0.08 ppm at all levels.
2. In 4 days the 8-hour average at the 1420 feet level exceeded 0.08 ppm when any of the other levels did not exceed that concentration.
3. There were no days when either of the three lower levels exceeded 0.08 ppm and the upper level did not exceed that concentration.
4. On seven days, the 8-hour average concentration at the ground level did not exceed 0.084 ppm when at least one of the upper levels did exceed that concentration.

Table 7 presents 24-hour average ozone concentrations at the four levels monitored for selected dates. These dates were chosen because at least one of the levels maintained an average 24-hour concentration greater than the new 8-hour average ozone standard of >0.084 ppm. The most frequent occurrence of a 24-hour average greater than this new 8-hr average 0.08 ppm standard value was at the 1420 feet level.

There is a definite pattern of lowest to highest concentration when going from ground level to the 1420 feet level for these dates. For each of these twelve days when the 24-

hour average ozone concentration at the 1420 feet was greater than the new standard, there was an ozone exceedance reported for the ground level monitor. The average ground level exceedance for these dates was 0.098 ppm ozone.

Figure 5 below shows the hourly ozone concentration data from 6 am July 26 through 6 pm July 28 (two of the dates from Table 7) for both the ground level and the 1420 feet levels. This is representative of the classical cycle of formation and depletion of ground level ozone. For presentation purposes only, the calibration cycles, 3 and 6 am, have been removed from this plot. The ground level ozone concentration begins increasing at 6 am, builds to a maximum value in the mid to late afternoon, and slowly declines throughout the evening hours.

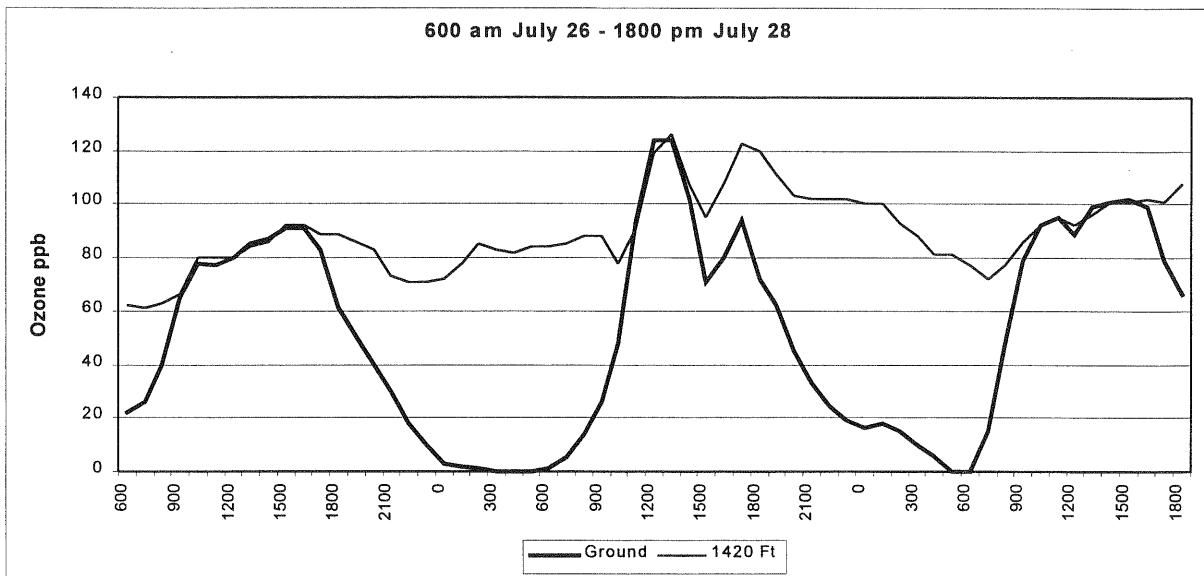

Figure 5. Tower Diurnal Cycle

In contrast, the 1420 feet level ozone concentration over this time period remains relatively constant at a considerably higher concentration. From late morning through early afternoon, the ozone concentrations at both levels are virtually identical.

A complete reporting set of Hourly Average Ozone data for each level and monitoring period is included in Appendix A. The following identifies the sampling elevation under the Parameter identifier in the Hourly Average Report in these reports.

Parameter	O3	Ground Level
"	M2	250 Feet
"	M4	420 Feet
"	Hi	1420 Feet

5.2 Volatile Organic Compound Results

Ambient air samples were collected for Volatile Organic Compound (VOC) analysis in the morning and afternoon from May 31 through September 8 at three levels of the Tower. These levels were ground level, 820 feet, and 1420 feet. The samples were analyzed the following week at the Ambient Monitoring Hydrocarbon Laboratory. A total of 63 samples were successfully collected, analyzed, and are included in this report. There were 24 samples collected at ground level, 17 samples at the 820 feet level, and 22 samples at the 1420 feet level. The collection of nine samples from the morning sampling period and 12 samples from the afternoon sampling period was unsuccessful. The data from the analysis of the ground level samples were reported to the EPA. The upper level samples were not reported to the EPA because these levels do not meet the EPA siting criteria.

The Total VOC determined in a sample includes methane, the 56 PAMS Target Compounds, and all compounds detected and quantified but not identified. The Total Non-Methane Organic Compounds is reported after the methane fraction has been removed from the Total VOC determination. The Total Unknown is the sum of the reported but unidentified portion of the sample. A summary of the results for the 1999 sample set in 1999 is in Table 8.

Table 8. Total VOC, NMOC, and Unknown, Min, Max, and Median Concentration (ppbC)

	Ground		820 Feet		1420 Feet		
	Am	Pm	Am	Pm	Am	Pm	
Number of Samples	13	11	11	7	9	13	
Total VOC	<u>min</u>	73	79	54	39	52	57
	<u>max</u>	272	168	126	163	174	106
	<u>Median</u>	99	107	71	91	65	81
Total NMOC	<u>min</u>	32	50	14	11	23	20
	<u>max</u>	233	139	83	133	141	60
	<u>Median</u>	69	67	34	62	32	46
Total Unknown	<u>min</u>	0	1	0	0	1	1
	<u>max</u>	8	9	4	10	10	10
	<u>Median</u>	2	1	2	2	3	6

The median NMOC concentration shows a distinct difference between the ground and upper levels in the morning samples. The ground level is roughly twice the concentration of both the 820 and 1420 concentrations. The median concentration for afternoon samples show a different relationship. Even though the concentration at all levels is greater in the afternoon both the ground and 820 foot level are a third greater

than the 1420 foot level. The Unknown Fraction in all samples on a per level basis shows the least variability, with a slight downward trend.

The identified NMOC fraction (the PAMS 56 Target Compounds) can be further broken down into the common classification of Paraffinic, Olefinic, and Aromatic compounds (AOP). There are 29 paraffins, 10 olefins, and 16 aromatics in the target compounds (which excludes methane). Acetylene, an alkyne, is the only target compound that does not fit into this classification and is listed separately in Table 9.

Table 9. Paraffin, Olefin, and Aromatic Distribution of Targeted Compounds

		Paraffins		Olefins		Aromatics		Acetylene	
		am	pm	am	pm	am	pm	am	pm
Ground	min	8	14	2	9	11	12	0	0
	max	124	52	43	48	66	36	3	2
	Median	24	18	9	27	33	15	1	1
820 Feet	min	5	4	1	4	7	4	1	1
	max	28	28	27	27	25	86	31	2
	Median	13	20	4	7	9	22	1	1
1420 Feet	min	10	9	2	3	6	3	0	0
	max	90	38	11	11	28	22	21	2
	Median	11	19	2	5	7	8	0	1

*note: results in ppbc

The vertical distribution pattern and relationships for the Paraffin and Aromatic compound classes is the same as total NMOC in the morning and afternoon samples. These two classes dominate the composition in the morning samples, but the Olefin fraction is the largest component at the ground level in the afternoon. It should also be noted that at all three levels the olefinic fraction increases from morning to afternoon. The seasonal acetylene levels were equal. An exception occurred with the maximum concentrations on the morning of June 21 at both the 820 and 1420 feet levels. These two morning samples had exceptionally high acetylene concentrations of 31 ppbc at the 820 feet level and 21 ppbc at the 1420 feet level. During 1999, a new 2000 feet+ tower was being constructed approximately 1000 meters to the southeast of the Auburn Tower. It is believed these exceptionally high acetylene concentrations are related to metal working activities on this new tower.

The major component of the Olefin fraction is **Isoprene**, which is greater in the afternoon samples at all levels. Isoprene is a highly photochemically reactive biogenic compound emitted by trees and grasses especially during warm weather. Figure 6. shows the morning and afternoon median concentration of isoprene and the other olefinic compounds for the samples collected in 1999. Isoprene dominates both the ground level and 1420 feet olefin fractions.

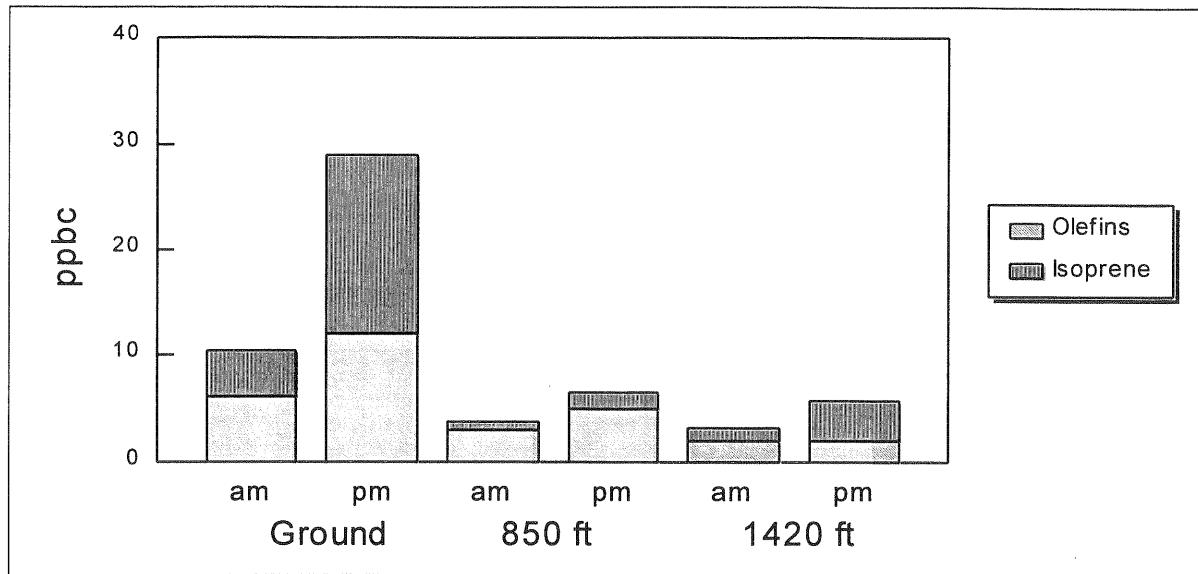

Figure 6. Diurnal Isoprene Pattern

All samples were analyzed for the 56 PAMS Target Compounds, methane, and unidentified components. Of the 57 compounds identified by this analytical technique, 16 compounds were found over 50% of the time in all samples. These compounds of highest frequency of detection range from methane (C1) through undecane (C11) and the percent detected is shown in Table 10.

note: Percent (%) found in samples

Table 11 below list the median 1999 concentration for each compound. In the morning samples, 54 of the PAMs target compounds were detected at the ground level, with 40 at the 820 foot level, and 46 at the 1420 foot level. In the afternoon samples, 49 of these compounds were detected and reported at the ground level, 47 compounds at the 820 foot level, and 48 compounds at the 1420 foot level.

Figure 7 compares the ground level median concentration for the morning and afternoon samples. Target compounds that did not change in concentration are not displayed. This plot shows the large increase in Isoprene and large decrease in Toluene concentration from morning to afternoon. The other compounds that show

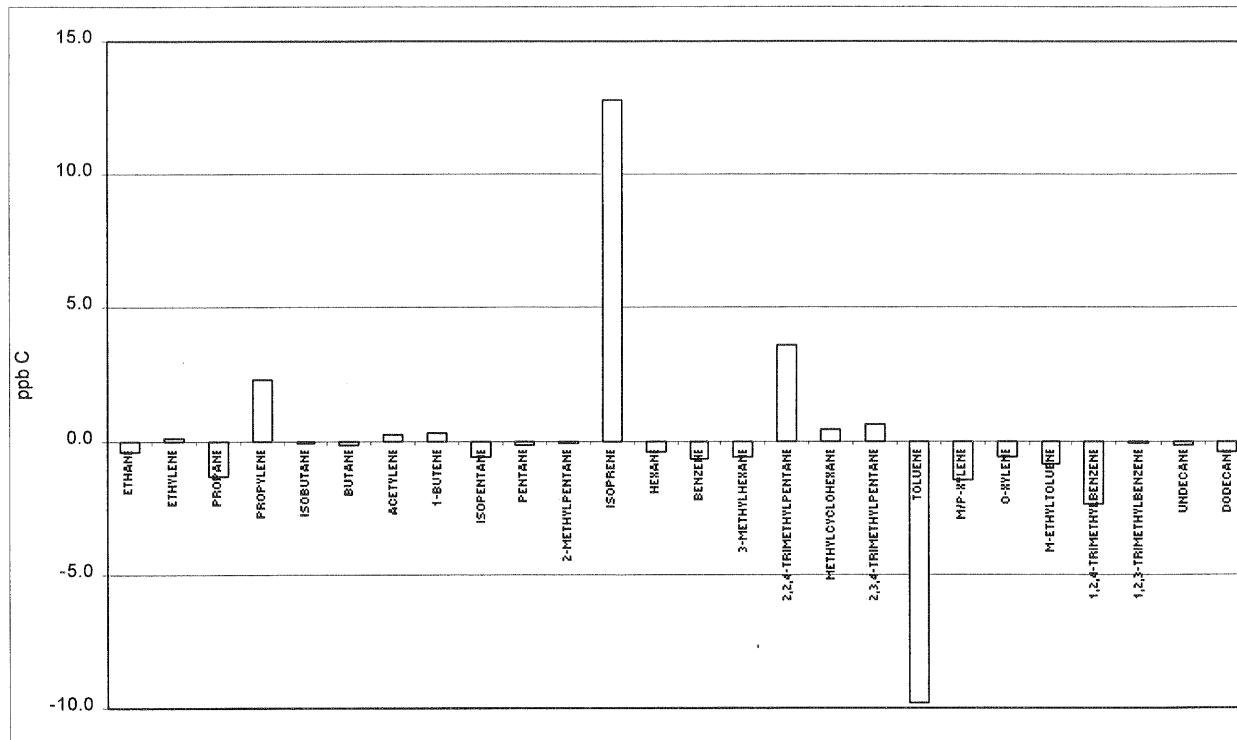

Figure 7. Change in Ground Level Concentrations from Morning to Afternoon

an increase from morning to afternoon at the ground level are Ethylene, Propylene, Acetylene, 1-Butene, 2,2,4-Trimethylpentane, Methylcyclohexane, and 2,3,4-Trimethylpentane.

The next two figures present the same comparisons at the 820 and 1420 feet levels for morning to afternoon median concentrations. In Figure 8, the morning to afternoon comparison for the 820 feet samples shows a different pattern than the ground level with a large number of compounds increasing in concentration in the afternoon. A total of 17 compounds increased in concentration at the 820 feet level in the afternoon. The increase in isoprene concentration in the afternoon was less than 1.0 ppb carbon. Toluene increased in concentration in the afternoon, whereas it decreased in the ground level comparison.

At the 1420 feet level, the afternoon concentration of seven target compounds increased as shown in Figure 9. Isoprene showed the greatest increase and Toluene showed the greatest decrease. This is a similar pattern as the ground level but the magnitude of change at the ground level is larger.

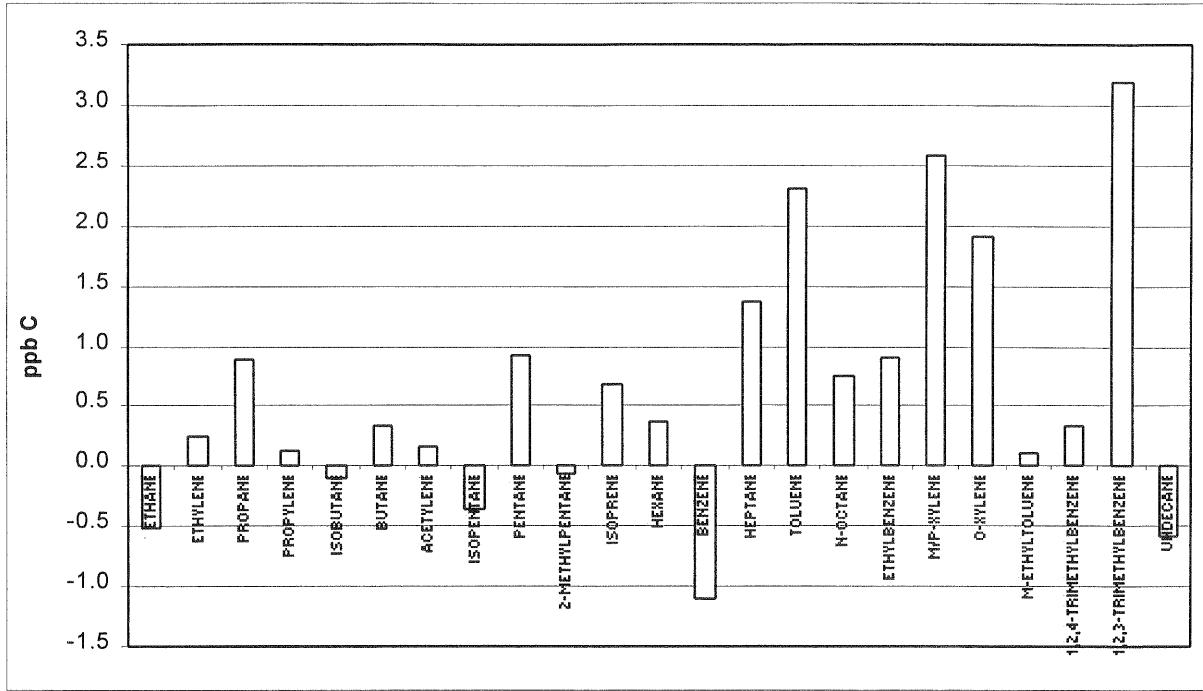

Figure 8. 820 Feet Level Change in Concentrations from Morning to Afternoon

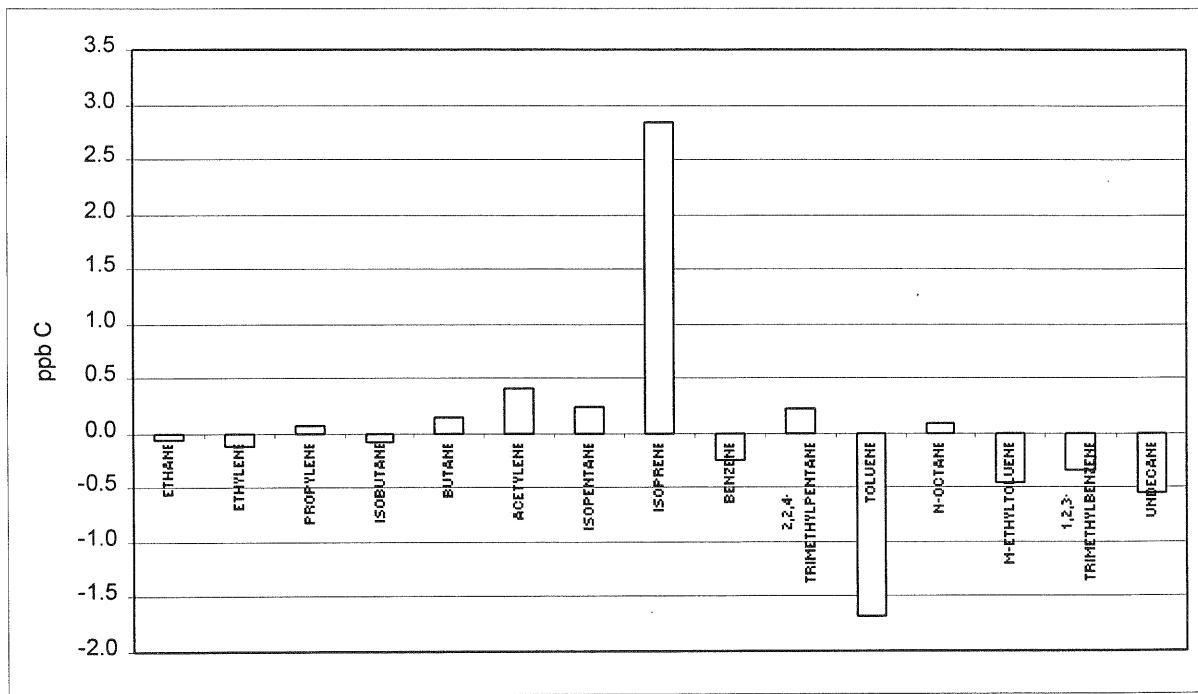

Figure 9. 1420 Feet Level Change in Concentrations from Morning to Afternoon

Figure 10 compares the composition and concentration of both the ground level and 820 feet level to the 1420 feet level for the PAMS Target compounds. This figure only contains the compounds where a detected difference in concentration was found. Using Toluene for an example this figure shows the ground level concentration of Toluene to be far greater than the concentration at the 1420 feet level. Likewise, this figure shows the concentration of Toluene to be greater at 1420 feet than the concentration of Toluene at the 820 feet level during the morning sampling period. In most cases, both the ground level and the 820 feet level are more concentrated for each compound than the 1420 feet level. Three compounds were found to have a

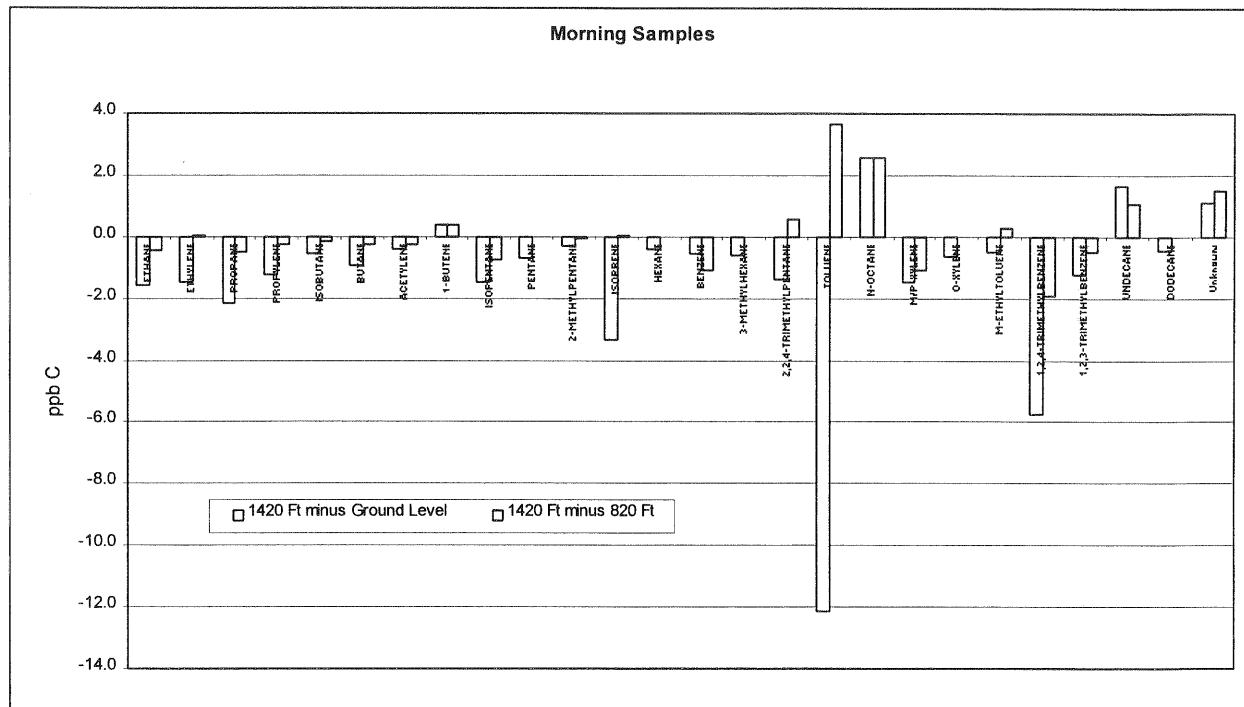

Figure10. Comparison of Morning PAMS Concentrations

higher morning median concentration at the 1420 feet level than at either the ground or the 820 feet level. These compounds are 1-butene, N-Octane, and Undecane. Another four compounds were found to have a higher median concentration at the 1420 feet level than the 820 feet level but not the ground level. The unknown component of the 1420 feet level is greater than either of the other two levels.

Figure 11 shows the same comparison for the afternoon samples. In addition to the same three compounds that were at a higher concentration in the morning samples for the 1420 feet level Isoprene shows a large increase at the upper level in comparison to the 820 feet level.

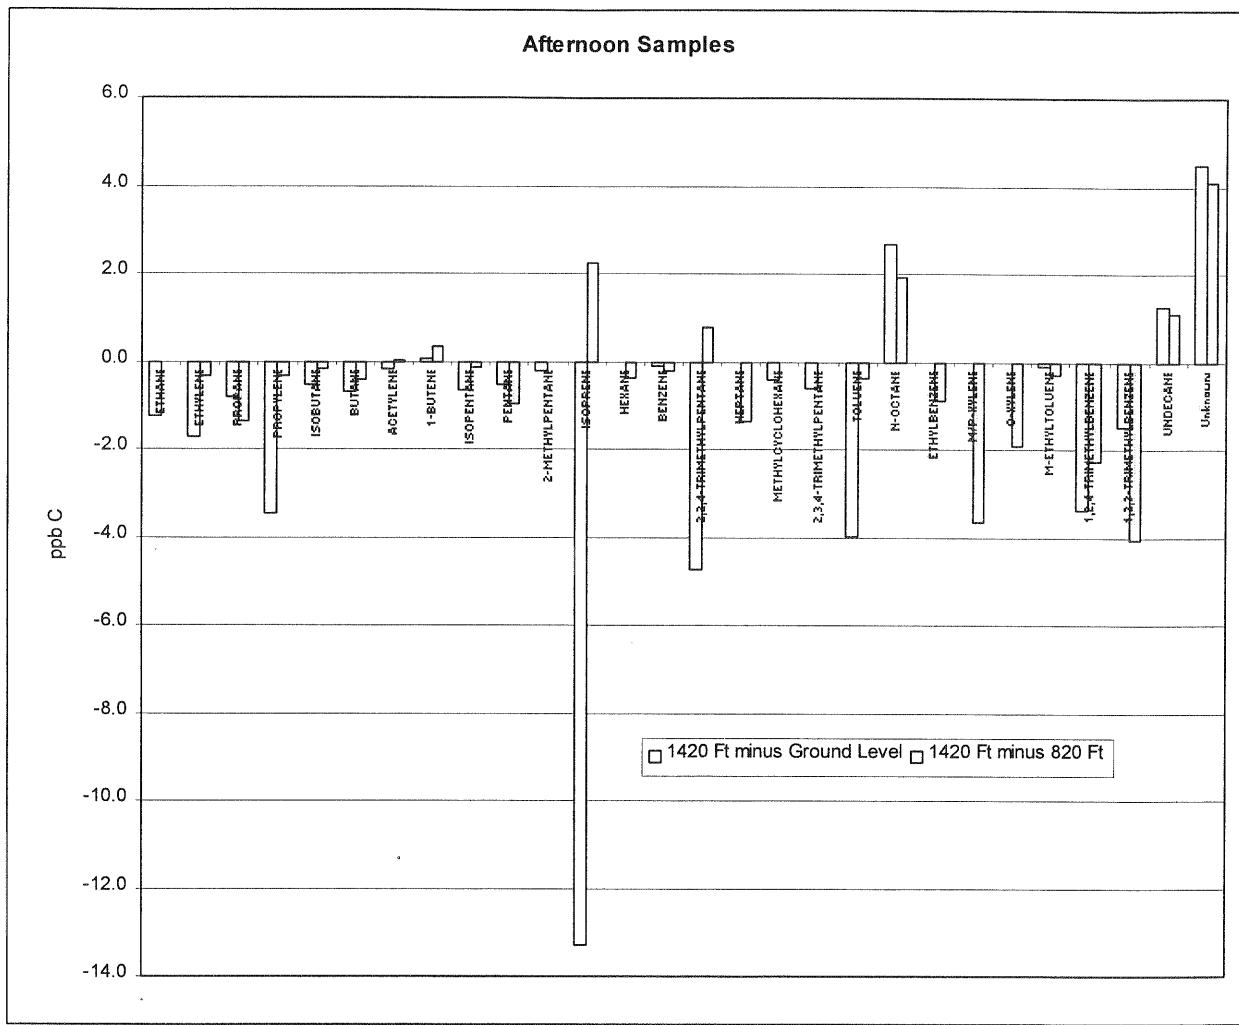

Figure 11. Comparison of Afternoon PAMS Concentrations

The complete set of the PAMS Hydrocarbon Speciation Reports for each level for each of the 13 sampling days in 1999 is included in Appendix B.
